Two threads ran through their lives. First, they studied social institutions with a view to transforming them. They were interested in knowledge only as a guide to and a precursor of action. Second, they were democrats bent on converting others to their way of thinking, and shirking no effort in education, propaganda, organisation, and agitation to achieve this. They were thus and above all practical people with an uncanny sense of what was practicable as well as desirable. I suppose one could say, therefore, that their approach was essentially English; and even in their latter-day conversion to Soviet Communism what attracted them most was the "marriage of dogma with a perpetual consideration of ways and means."

Was it their own near-perfection that led them, perhaps, to under-estimate the human element in all this planning? Mrs. Cole describes as their major weakness the insufficient attention they paid to the problem: Who would run and tend the machine of their welfare State? Today, as each new situation arises, whether it be that of caring for deprived children or managing regional hospital boards, we have no opportunity to forget how much we depend on those who administer the law.

* * *

When I tell him that I got a credit in arithmetic in the School Certificate of 1918 and that I often give my boys in form II and IIIa some useful tips with their maths homework Mr. Patrick Slater will no doubt be glad of my opinion on a point in his *Survey of Sickness.*

In a total sample of 6950, he says, "5518 of the subjects (79%) suffered an illness of some kind . . . and 263 (4%) suffered an injury; 185 (*only 70% of those injured*) suffered illness as well as injury. Hence illness and injury do not go together; healthy people are more likely to be injured than ill people are. When they are well, people are exposed to risks of injury on the roads and at their places of work to which they are not exposed when ill; therefore this finding is in accordance with reasonable expectations."

I'm with Mr. Slater in thinking that rest in bed is the finest preventive against being run over, but surely his calculation (my italics) doesn't show that. He should have told us that the 185 was only 3·3% of those ill. What the present one shows is that uninjured people are more likely to be ill than injured people are, which isn't quite so obvious; I suspect the small difference really shows that when you have lately had an accident you are not so keen to tell the interviewer all about your colds and rheumatics.

* * *

The political views of my sister-in-law are not those of the majority, but her remarks on social phenomena gain in vigour from this dissonance. In her last letter she has a few bitter comments on the effect of social legislation on the habits of Maoris in New Zealand. Apparently the Maori has received with gratified and gratifying enthusiasm the family allowance of ten shillings a week per child. This has enabled many a family man to retire and live a life as carefree as any debenture holder, and permits him to concentrate on the congenial and productive task of increasing his income. This is shocking enough to anyone with old-fashioned views on the distribution of wealth, but she complains further that it is now impossible to find a taxi. The Maori, with a pleasant, naïve, and absorbing passion for taxis, spends much of his newly acquired wealth in the easy transit from one social event to another. The sting comes in the tail of the letter. My sister-in-law, who lives near a large Maori *pah* (i.e., village) spends most of her day admitting engaging and smiling Maoris who want to use her telephone to call a taxi.

* * *

When we were going through the addresses and phone numbers of my colleagues my new secretary asked how she was to know which was a suitably equipped anæsthetist (they are all well qualified) to book in a hurry. We decided that the R.A.C. and A.A. method would be best, so now they are starred like the hotels. A **** stuffist must have a closed circuit, cyclo, and curare, be au fait with adrenaline drips, and be able to engage the onlookers in conversation on abstruse physiology when I am in a tight corner: naturally, like the hotels, he will be the most expensive. For *** a closed circuit and a knowledge of spinals will do, with of course an *eccentric* nozzle syringe for his thiopentone. The ** man must have a Boyle's and be able to use thiopentone too. A * anæsthetist has no machine of his own but is safe on the hospital one. We don't feel that I shall ever need a ***** man, but you never know. I'm just off after dinner to do a job with a "local."

* * *

Dear Old Lady: "As you know, Doctor, I cannot afford to have you calling as often as I would like, but when the new Health Service comes into force I shall want you to visit me every morning at half past eleven."

Where necessary, the prostatic cavity can be packed round an indwelling catheter; and the free end of the gauze ribbon is firmly secured by two separate strong silk sutures to the expanded end of the de Pezzer catheter, which for this purpose is pulled into the bladder and out through the prostatectomy incision, and is then pulled back till it lies snugly against its drainage-hole in the bladder wall.

The closure of the lower opening in the bladder has to be done with some care to make it watertight. A continuous catgut side-to-side stitch is started at the upper end, just missing the mucosa, and when it reaches the lower end it is carried back upwards at a more superficial level; indeed it is probably better to continue it down again as a third layer at a still more superficial level to avoid the possibility of leakage. An ordinary continuous suture has not proved leak-proof, perhaps because it interferes with the arterial supply of the bladder wall, which runs vertically from the base. The usual drain to the space of Retzius is inserted and the incision closed.

The above procedure needs no special instruments or skill; if packing is used, it is pulled out on the fourth day by removing the de Pezzer catheter, but the latter should be replaced. The patient remains dry till the de Pezzer is removed on the tenth day. Leakage may occur for a time through its drainage track, but by this time the patient has got well over the worst part of his convalescence and leakage often ceases in two or three days.

Birmingham. J. W. RIDDOCH.

THE ESKIMO'S TEETH

SIR,—In your annotation of April 26 you referred to the findings of Dr. Pedersen in Greenland, that the natives who take to the carbohydrate diet of civilisation suffer from dental caries, while those who keep to their normal diet of meat and fish have healthy teeth. You quote him as saying: "In my opinion we are not entitled to draw far-reaching conclusions from these studies as to whether the tooth structure or the carbohydrate factor plays the greater part."

In his *English Social History* Prof. G. M. Trevelyan states that "foreign and native travellers in Tudor England marvelled at the number and size of the flocks [of sheep], unparalleled elsewhere in Europe." He speaks of the "prosperous and hospitable generation, whose carnivorous habits amazed foreign visitors accustomed to a more farinaceous diet." This rich meat diet could hardly have been confined to the really well-to-do, as he mentions that "Rugby abounded with butchers."

Is enough known, from records or the study of skeletons, about the state of teeth in England and on the Continent during the Tudor period, to say whether caries was more prevalent in the latter area? While not proving that a carbohydrate diet is responsible, evidence of pronounced difference between English and Continental teeth at that time would be suggestive.

Royal West Sussex Hospital, Chichester. C. J. HARWOOD LITTLE.

CLICKING PNEUMOTHORAX

SIR,—Dr. Thompson's article in the issue of May 10 prompts me to record my own experience.

Two months ago pulmonary tuberculosis was diagnosed (left hilar region). An artificial pneumothorax to a pressure of −3 cm. was induced, and three days later a refill was done. It was then that I first noticed this curious clicking sensation. Lying on my back, I could hear it distinctly and could feel it in the 4th intercostal space, just to the left of the sternum. When lying on my left side, I noticed that the clicking sensation shifted somewhat to the left, being still distinctly palpable and audible. Auscultation revealed a kind of bubbling sound, as if fluid were being disturbed in a confined space. A point of interest is that the clicking was quite unrelated to ventricular systole, thus differing from Dr. Thompson's cases. However, having had several further refills I have noticed that the noises are now synchronous with systole, and that they come and go in spasms.

I may add that radiologically there is evidence of adhesions, and it will be interesting to see whether these sounds disappear after division of the bands.

MEDICO.

BRONCHOSPASM AFTER CURARE

SIR,—The attack of bronchospasm after cur observed by Dr. Donovan (May 10) in a patient subject to bronchial asthma, may have been due to a release intracellular histamine, caused by the injection of curare. In animals (dogs) the injection of *d*-tubocurarine causes a release of histamine from striated muscle into the circulation, and a similar phenomenon may possibly occur in man. Asthmatic patients are said to be unusually sensitive to the bronchoconstrictor action of histamine. It would be interesting to know whether attacks of dyspnœa after curare in patients liable to bronchial asthma have been observed by others.

Such an attack might possibly be prevented or arrested by one of the new anti-histamine drugs. As you say in your leader of May 17, these drugs counteract experimental bronchoconstriction produced by histamine. Unfortunately they have been reported to produce a paradoxical bronchoconstriction of their own in a small proportion of allergic patients.

Liverpool. R. A. GREGORY
London. H. O. SCHILD.

LINING OF THE PULMONARY ALVEOLI

SIR,—The leading article in your issue of Jan. 11 was timely, and should stimulate further research on a fundamental lung problem which has baffled investigators for a century. To me the crux of the matter is the nature of the covering of the "bare areas"[1] which have been thought by some pneumonologists to be occupied by thin films of epithelial protoplasm called "squames" or "non-nucleated plates," though in sections of normal mammalian lungs no epithelial cells can be seen upon them. Miller[2] and Bloom[3] have pointed out that this surface covering has never been seen after desquamation. I recently thought I had stripped these hypothetical elements from the alveolar walls of mouse and other mammalian lungs, but a careful re-examination of the slides has convinced me that I was dealing with what are technically known as "smudges," though of unusual appearance. I did undoubtedly succeed in stripping off bits of the epithelial layer from the finer bronchioles and found in places extending from their edges curious, extremely thin flanges of substance which I thought to be underdeveloped squames forming part of the lining of the smaller alveoli which jut off from the walls of the respiratory bronchioles, for they corresponded in position to the larger fields circumscribed by dark lines in lungs which had been treated with dilute silver nitrate and afterwards exposed to sunlight or photographic developer, and their appearance was in keeping with my conception of what a respiratory squame would look like. However, I now regard them as smudged epithelial cells.

These exfoliations of epithelium were found in preparations made by what I have termed the "gash-irrigation" or "G.I." technique. In this, cuts into the fresh exsanguinated and collapsed lung are made with a safety-razor blade through a drop of physiological saline solution placed on the pleura, thus flushing the air-spaces. The preparation is then inverted and the emerging drop, carrying with it loose cells from the air-spaces, is received on a glass slide and is spread and stained with Wright's or Giemsa's mixture like a blood smear. In these preparations were also found many bodies of similar nature to those described as attached to the desquamated epithelial sheets, but differing in being usually of larger size, and in lying isolated in the field. Many were obviously modified cells with thinned nuclei from which thin processes projected to one side or all the way round. The edges were so thin as to be almost invisible. Some had no nucleus, but only a darker area in the central region to mark its place, while in others even this trace was wanting. It was easy to arrange from these objects a series, graduated according to the degree of nuclear attenuation, from small cells with a relatively intact nucleus through intermediate forms of increasing width but with a disappearing nucleus, down to wide, vignette-

1. Macklin, C. C. *J. thorac. Surg.* 1938, 7, 536.
2. Miller, W. S. (In Cowdry's Special Cytology, New York, 1947, sect. v, p. 133).
3. Bloom, W. (In Maximow and Bloom's Text-book of Histology, Philadelphia and London, 1947).

hird showed areas of focal infiltration and necrosis near he *lateral ventricles*, *perivascular cuffs*, and infiltration in he ependyma; but similar changes were found in its mother nd a twin examined as controls, as well as in two other ontrols. No abnormalities were seen in the brains of three ats inoculated with filtrate of normal brain of a cat or n twelve normal controls. The results of bacteriological nvestigations were inconclusive.

It was suggested that cats are liable to be infected ith neurotropic viruses and may therefore act as a eservoir from which the infection could be transmitted o human beings.

The number of animal species known to be affected by arious virus diseases is increasing, and much has recently een learnt on the links between man and animal infecion. The cat appears to have been strangely overlooked n these studies. Dr. G. H. Jennings in his paper of pril 12 states that many homes from which his patients ere coming had cats. It may well be worth examining ome of these cats, and generally paying more attention o this animal.

Epsom. WILLIAM N. ROGERS.

CINEPLASTIC OPERATIONS

SIR,—In recent issues I have read with considerable nterest several articles and letters concerning the value f cineplastic operations for amputation of the upper xtremity.

As an exponent of this method in the United States for the past twenty years, I have always taken the view that there is no one device or procedure that can answer the needs of every arm amputee. My practice has been to employ cineplasty along with other devices such as the utility hook, the mechanical hand, or other special mechanical prosthetic appliances as a reservoir from which we can select the one which will best fit the needs of each specific case. In my opinion the device or method must be fitted not to the person's stump but to his whole personality, bearing in mind the psychological and vocational as well as the economic aspects.

Regarded in this way, we will find that cineplasty has its place as a special measure to meet the needs of special persons rather than as a solution to the problems of all amputees.

Newark, New Jersey. HENRY H. KESSLER.

HÆMOLYTIC DISEASE OF THE NEWBORN

SIR,—May I comment on your interesting annotation (April 5), and on Sir Leonard Parsons's letter (April 19)?

Nomenclature in hæmatology is notoriously vague; indeed it does not appear to be clear what each hæmatologist means by an erythroblast. May I suggest that instead of "hæmolytic disease of the newborn" there be a new classification under the heading "Rhesus diseases of the newborn," to include (i) erythroblastosis or congenital anæmia; (ii) icterus gravis neonatorum; and (iii) hydrops fœtalis. Such a classification does, I think, agree with present-day knowledge. In (i) the antibody has attacked mainly the hæmopoietic system of the child, and the disease is a hæmolytic congenital anæmia. In (ii) the liver cells and, either primarily or secondarily, the brain and extrapyramidal cells are attacked by the antibody or antibodies; this is essentially a toxic condition, unconnected with hæmolysis. In (iii), the gravest of the diseases, the antibody has attacked all the internal organs, with the well-known result of stillbirth or an œdematous, peeling, fœtus destined to live only a few hours. In these three conditions it may seem that the maternal antibody, whether single, compound, or incomplete (blocking), may be selective for certain tissues.

Regarding treatment, surely Sir Leonard Parsons would not suggest that the logical treatment of a severe case of icterus gravis, where, as often as not, there is no anæmia, is to transfuse with Rh-negative blood "to correct the anæmia." Exsanguination transfusion is no new treatment; many years ago it was practised by Sir John Fraser, in Edinburgh, for the treatment and prevention of shock due to burns.

Finally, in respect of mortality, Sir Leonard gives a figure of 27% for these babies at his clinic since he started to transfuse Rh-negative blood. In my own small series, since 1942, the mortality is nil, but in view of the unfortunate incidence of kernicterus I would have welcomed a mortality of more than 27%. To my mind it is the end-result that matters, not the immediate mortality; and further careful consideration of children two years after survival of the disease is needed.

Nelson, Lancs. HENRY THIRD.

CHILD GUIDANCE IN OLD AGE

SIR,—The meshes of the net spread by Professor Mackintosh in your issue of May 17 are a little too plainly visible. Chaff will not trap the wary old bird.

I appreciate the spirit of mischief that has crept into the latest of his pastoral letters; but will he tell us, who have changed our occupation at 65, how to recognise that even for the new task our powers have become inadequate and a proper opportunity for ridicule by our loved young ones?

Perhaps, after all, I am enmeshed in his snare!

PHOENIX.

ADVICE ON THUNDERSTORMS

SIR,—Your note on thunderstorms (May 17, p. 682) interested me. I would like to describe the precautions taken by a family I once knew. To permit fireballs to pass safely through the house without striking off their legs they used to open doors and windows and sit with their feet on the table. These precautions were invariably effective. In addition the mother encouraged her children by the assurance that every flash or bang meant that the storm was a hundred miles farther off. I believe they heard storms raging in New York or Siberia. This assurance was also effective and none broke down under the strain.

Colchester. G. C. PETHER.

TECHNIQUE OF PROSTATECTOMY

SIR,—The correspondence following the article by Mr. Terence Millin [1] introducing retropubic prostatic adenomectomy showed the interest in methods of curing prostatic obstruction. The bulk of prostatectomies are, no doubt, carried out by general surgeons, and the non-urologist has at times to steer his barque into a somewhat ammoniacal breeze and navigate the narrows of the bladder neck. Some of those who do not specialise in urology have not the opportunity or inclination to acquire the special skill called for outside the old-fashioned suprapubic enucleation, the disadvantages of which are the wet condition of the patient, the frequent changes of dressings after operation, the unsightly scar, and sometimes a subsequent ventral hernia. These disadvantages can be largely avoided by adopting the well-known surgical principle of draining through an incision separate from the main operative one—a method I have been using for about three years.

In the one-stage operation a median incision is made from the pubes to near the umbilicus, the prostate is enucleated through a vertical incision low in the bladder, and the bleeding is controlled by irrigation or packing. With the help of two fingers in the bladder, the peritoneum is stripped as high as possible so that the anterior part of the dome of the bladder as it recedes backwards is laid bare; a de Pezzer catheter is inserted through a stab-wound in this region, and the hole made watertight by a circular catgut suture; the catheter is then brought out by a track made through either rectus muscle and sheath and a skin stab, so that it passes obliquely upwards to one or other side, coming out just below the umbilicus.

In the two-stage operation, the first stage consists of an incision starting about one inch above the umbilicus over the right rectus muscle and passing downwards and medially to about two inches below it and towards the midline. Where the bladder is not large, the downward extension may have to be greater. The anterosuperior surface of the bladder is laid bare and the de Pezzer catheter inserted as above. This leaves the area immediately above the pubes free of adhesions, a virgin field for the actual prostatectomy. At the second stage an incision of the Pfannenstiehl type is preferred; this is a transverse incision about one inch above the pubes through the skin and rectus aponeuroses, with separation of the rectus muscles. The prostate is removed through a low bladder-incision. Alternately, a vertical incision, inclining to the left as it passes upwards, may be used.

---

[1] *Lancet*, 1945, ii, 693.

Organisation is an inevitable concomitant of social evolution. Social life in a democratic society requires the harmonious integration of the activities of all sections of the community. The objection that such integration is incompatible with freedom or individuality has little substance. Scientists cannot but gain freedom and inspiration from becoming more socially conscious in outlook.

"My kingdom is not of this world" is an inappropriate credo for scientists in the atomic age.

London, N.W.3. Martin Roth.

HOSPITAL WARD PLANNING

Sir,—Dr. McIntosh and Mr. Coales (May 10) have produced a very timely and interesting ward plan. They are to be congratulated on combining as far as possible the best features of modern planning in one composite whole. In my view, the Medical Research Council's War Memorandum no. 11 on the control of cross-infection in hospital will have a profound effect on the ward planning of the future. Whilst it emphasises the need for isolation cubicles with access from corridors, it at the same time stresses the importance of good lighting and ventilation, especially in the control of droplet-borne infection.

The design submitted has another desirable possibility not mentioned by its authors. Often there is a great demand for beds on the male side while there are empty beds on the female side, or vice versa. This plan allows for elasticity in the allocation of beds between sexes even within the same ward unit. The provision of two separate sanitary units would help segregation.

I believe, however, that a ward of 30 beds is too big, at least for an acute general hospital. Complicated modern procedures demand that the ward sister should only have about 20 patients to look after. I agree with Dr. McIntosh and Mr. Coales that the 2-bedded unit has no merit either from the patient's or the hospital's point of view.

Llandough Hospital, Cardiff. David G. Morgan.

INFECTION BY INJECTION

Sir,—In your leading article of May 17 your rightly draw attention to the serious dangers attending the use of improperly sterilised syringes.

Discussing the limitations of autoclaving or adequate dry heat when sterilising glass-metal syringes you say that:

> "Boiling, however, is within the scope of all; and boiling is perfectly satisfactory provided the syringes and needles do not remain in water exposed to the air, and are assembled with forceps or sterile gloves."

I think this description of boiling as being "perfectly satisfactory" needs further qualification. The Medical Research Council's War Memorandum no. 15 (1945) refers to the technique of boiling in the following terms:

> "Boiling in water will destroy all pathogenic bacteria *except those that produce resistant spores*. . . . The word 'sterile,' therefore, applied to a syringe and needle, implies that the syringe and needle have been through the process of sterilisation in the autoclave or hot air oven. It is often loosely applied to a syringe that has been boiled. Since accidents due to spore bearing bacteria have proved rare, a boiled syringe may be accepted as reasonably safe where sterilisation in the autoclave or hot air oven is impracticable, but a boiled syringe is not necessarily sterile and its safety cannot be absolutely guaranteed."

It is clear from this that boiling is far from perfectly satisfactory, and that every effort should be made to sterilise syringes by autoclave or hot-air oven, especially when they are to be used for intrathecal injections.

Hertford County Hospital, Hertford. John C. H. Hanson Chief Pharmacist.

DIETARY DEFICIENCIES IN HONG-KONG

Sir,—May I correct one or two details in your annotation of April 26, which was based on my report on Medical and Health Conditions in Hong-Kong, 1942–45?

It is not true that British, Americans, and *Indians* were interned in Stanley Civilian Internment Camp. Several hundred Indian troops were interned in a P.O.W. camp on the Kowloon Peninsula and several were imprisoned in Stanley Prison; but none were inte in Stanley Camp. Dr. Fehily's article in the B *Medical Journal* (Feb. 8, p. 220), to which you re is not quite accurate in all particulars. For exam the infant-mortality rate in Hong-Kong for 1946 109 not 100.

Lastly and more important, neither I nor my coll would like it to be thought that we claimed to responsible for the remarkable health record for 1946. In this the first complete year since the liberation of the colony from the Japanese the general death-rate, the infant-mortality rate, and puerperal morbidity and mortality rates were the lowest recorded since the colony first came into being in 1841. This achievement, in the face of real difficulties, is the result of team-work in which medical, health, investigational, and social-welfare services share the credit with the able administrators responsible for maintaining food-supplies, the water and sanitary engineers, and the Navy, Army, and Air Force personnel. The relief workers mentioned, who undoubtedly helped to achieve the satisfactory results, included those attached to voluntary organisations, such as the Red Cross, Salvation Army, the Hong-Kong Social Welfare Council, and the Society for the Protection of Children, as well as members of the relief section of the Hong-Kong government medical department.

London, S.W.19. P. S. Selwyn-Clarke.

Parliament

ON THE FLOOR OF THE HOUSE

Despite protests at the amount of work the House is expected to complete, the work is being done. In the old days of the Irish party organised obstruction took a very big part in prolonging sittings past any reasonable hour. But these obstructionist tactics had only a limited aim—Home Rule for Ireland. Obstruction could succeed then as it cannot succeed now. For no one party dare hold up the work of the nation by making legislation impossible. Parliament in the old days was a largely political machine; now it is largely concerned with economic changes, and while many wish to amend very few would dare to oppose wholeheartedly. Economic changes on a big scale must be carried out, as the latest Conservative programme agrees. And so while disagreeing we progress. In the last week before the recess the House has passed the third reading of the Town and Country Planning Bill, the National Service Bill, the Statistics of Trade Bill, and the National Health Service (Scotland) Bill. For good measure there was added the second-reading debate on the Finance Bill, and a day of Adjournment motions.

Parliament will go on at this rate until the summer recess, which, rumour has it, is to be longer than of late and will last into October. It is to be hoped it will, for tempers are getting frayed even in the House of Lords. Under the Labour dispensation the Upper Chamber has become a more important organ of discussion and debate than for many a long year. Many new peers have been created who are able to take a leading part in public affairs, and this applies to all parties. Further, the power of initiating legislation which resides in the Lords is useful when the House of Commons programme is so crowded, and the power of revising the drafts of Bills sent to the House is useful when an extra time is needed for discussion.

The Addison-Cherwell mêlée on the feeding of the British people brought party politics very much to the fore in the usually august calm of the Lords. Mr. Churchill said some time ago that the people of this country are badly fed, and Lord Cherwell, who as Professor Lindemann was Mr. Churchill's adviser during the war, argued that our nutritional condition is very bad indeed, quoting the phrase "dying of starvation" from an article in a medical weekly. Lord Woolton intervened to say that this phrase was used in the strictly technical sense, but did not explain how death in a strictly technical sense differs from normal dying. Lord Addison vigorously rebutted Lord Cherwell's attack, and the old reputation of the House of Lords for quiet is shaken. But it is very unlikely that the Conservative Lords, who have a majority edged films of 35 μ or greater diameter, and with no nucleus. These were at first taken to be the long-sought respiratory squames in various stages of development, with the large anuclear ones representing the non-nucleated plates of Kölliker which had presumably been peeled off from the walls of the alveoli in the flushing process, just as had been the epithelial patches from the walls of the smaller bronchioles. However, critical study has convinced me that all of these formations are the result of "smudging" of cells. So close was the simulation of these artefacts to supposed reality that I reported them as detached squames to a scientific organisation,[4] and I wish to take this opportunity to set matters right, for I feel now that they are not respiratory squames. This "riddle of the lung" as you well term it in your editorial remains for me unsolved. We may thoughtfully parody the first line of John Keats' Sonnet on Fame and make it read: "Squame, like a wayward girl, will still be coy."

London, Canada. CHARLES C. MACKLIN.

W.H.O. AND GREECE

SIR,—Undoubtedly we all welcome the development of the World Health Organisation. There can be no dispute over the international importance of the many huge problems of disease prevention and raising of health standards, which it has set itself to tackle at the international level. In these undertakings we wish it godspeed.

But there is one aspect of its programme which should, I think, be seriously questioned—namely, that of two countries chosen for special missions on the spot, one of them should be Greece. I worked for sixteen months with the health division of the UNRRA Greece Mission, both in Athens and in the provinces, and it is hard to convey the extreme frustration experienced by all UNRRA field workers in their efforts to assist the reconstruction and improvement of services for the Greek people. The need was beyond measure; medical supplies and equipment arrived in abundance; great numbers of ordinary Greek citizens were ready to coöperate wholeheartedly and disinterestedly. Yet very little other than pure relief measures could be achieved, for the main reason that the Greek government put politics—its own particular brand of politics—before the interests of the people.

For instance, in the area of Corinth there is a very high incidence of trachoma, up to 70 % in some of the villages. A paper scheme existed to deal with this appalling situation. The only local ophthalmologist capable and willing to operate the scheme was not appointed to the post because his political opinions did not conform to those of the government. That doctor is now uselessly in exile, while the trachoma problem continues unchecked. For similar reasons many X-ray plants and laboratories installed by us go unused or only partially used. A number of girls put through emergency training courses for vital sanatorium nursing were subsequently refused appointment on the same grounds. Such examples could be quoted ad nauseam. But perhaps the most shattering incident of all occurred when the Greek government was fully prepared to wreck—and to some extent succeeded in wrecking—the huge lifesaving anti-malaria programme, in the course of conducting among its employees this same "purge" of "politically unreliable" elements.

I am told that in Poland unrelenting Nazis are reluctantly maintained in specialist posts where absolutely required by the acute shortage of experts. The Polish government can put the interests of reconstruction before the elimination of real enemies. Yet the Greek government will not employ even the humblest clerk if he helped to resist the German occupation.

Anyone who heard Dr. Marc Daniels speaking recently to the Tuberculosis Association about UNRRA tuberculosis work in Europe will appreciate how other countries —notably Poland and Yugoslavia—devastated by war beyond all comparison with Greece, suffering far more acute losses of trained personnel, and much less generously supplied by the United Nations, have yet made real, and in my opinion astonishing, advances towards restoring and developing their shattered health services. I would be the last to deny the Greek people that help which they certainly need and deserve. But I think that under present conditions in Greece the World Health Organisation will be as little able as was UNRRA to provide help from which the population will derive secure and lasting benefit. The taxpayers of the United Nations should have their money invested where returns in terms of real improvement of health conditions are certain. And if the World Health Organisation is to become the effective and respected body which we would like it to be, such considerations should be taken into account.

London, N.7. JUDITH WATERLOW.

EYE OPERATIONS ON THE DEAF

SIR,—May I make a plea for more imaginative dealing with the totally deaf (those who "hear" only through their eyes) while they are undergoing treatment in ophthalmic hospitals, especially after operations, when they have both eyes bandaged? To anyone lying in one position, fully conscious, deprived of sight as well as hearing, and not certain that sight will return, twenty-four hours can seem an eternity.

Through the sense of touch, used in ways arranged with the patient beforehand, something can be done to help. The time to the nearest hour can be tapped into the patient's hand; simple questions can be answered by a grip of the hand for "yes" and a shake of the hand for "no." (A slight movement of the patient's bed before the hand is touched will prevent shock.) It is also a help to know beforehand what nourishment will be given, and how; and to be told that you will not be left alone longer than an hour at a stretch (even though you don't ring) creates confidence.

While the patient can use his eyes, writing is the surest means of communication and should be used to tell anything important—that the time of the operation has been altered, for example. There will then be no waiting with nerves unrelaxed for preparations to begin, and no hustling of the patient which is not understood and causes worry. The operation itself, performed under a local anæsthetic only, is a great tax on nerves, and the avoidance of strain beforehand is an important matter.

London, W.2. GERTRUDE M. MANN.

ACADEMIC FREEDOM

SIR,—Professor Polanyi described the moral strength of the scientist as dependent on speaking "to the State as a liegeman of a higher master, demanding homage to this master." This is presumably the method he advocates for combating the ban already in operation on publications in certain fields of atomic physics, and which is likely to extend, if the present state of affairs continues, to an ever-widening field of scientific subjects, for there must be few discoveries of importance concerning which secrecy could not be demanded "in the national interest." While this approach carries a certain emotional appeal, it contributes little to the solution of the serious problems now confronting scientists, among them the threat to that free communication which is the very lifeblood of science. One is reminded of Canute sitting with his feet in the water forbidding the flood of the tide.

Professor Polanyi asks for the pure scientist an absolute freedom to dedicate himself "to the service of a transcendent reality"; he wants him to be free to follow his "personal creative passion." It is doubtful if the absence of restraint he would thus achieve could be characterised as freedom. No "metaphysical assumptions" will suffice to relieve the pure scientist of the burden of some moral responsibility for the consequences of his work. He cannot escape from them by retiring into a spurious isolation and making his utterances from academic solitude. The pure atomic physicist cannot retain purity and remain on his pedestal, wrapped in his transcendental vision while civilisation is exterminated with atomic bombs. Hiroshima and Nagasaki have made the problem of the perversion of science inescapable for scientists. They are henceforth morally obliged to study the social implications of scientific work and show their concern for truth and justice and all that is best in humanity by working for a rational social order in which scientific research, pure or applied, can result only in human betterment.

[4] Macklin, C. C. *Anat. Rec.* 1947, 97, 38.

was well as long as everyone got an equal amount of food, and seemed to prefer parity to charity.

National Health Service (Scotland) Bill

Before rising for the Whitsuntide recess the House of Commons agreed to the Lords' amendments to the Bill and the measure was given a third reading and received the Royal Assent.

QUESTION TIME

Free Meals and Milk

Replying to a question, Mr. G. TOMLINSON stated that according to the return made for a normal school-day in October, 1946, the number of pupils receiving free school meals in maintained schools on grounds of financial hardship was 338,450. The number of pupils in maintained schools receiving ½ pint of milk, which was free of charge for all pupils, was, on the same day, 4,369,000.

Speech Therapists for Schools

Mr. TOMLINSON also stated that 90 local education authorities are now employing speech therapists; 56 authorities have no speech therapists on their staff. Local education authorities generally are fully alive to the importance of employing such officers, but unfortunately the supply of speech therapists falls short of the demand.

Vaccine Experiments on Children

Mr. PETER FREEMAN asked the Minister of Health whether his attention had been called to the experiments on 600 babies in London and Manchester by injecting them with different varieties of vaccine; what the exact contents of each of these vaccines were and how each was obtained; what evidence there was that any of them had any effect on maintaining the normal health of the baby; who authorised these experiments; and what compensation would be paid to the children or their parents in the event of undesirable consequences.—Mr. A. BEVAN replied: This is an investigation conducted under the ægis of the Medical Research Council, in association with my medical advisers, into the value of certain vaccines in preventing whooping-cough. Trials in the United States suggest that these vaccines give protection against the disease and thus help to maintain the normal health of infants. This valuable test is being carried out with the voluntary agreement of the parents, and under strictly controlled conditions. There is no reason to fear ill effects.

Public Health

Tuberculosis in the Boot and Shoe Trade

Dr. C. M. Smith's survey in Northamptonshire[1] shows that the boot and shoe trade has an unusually high incidence of active pulmonary tuberculosis as revealed by mass radiography. It will be recalled that in 1915 a committee on the incidence of phthisis in relation to occupation found that "phthisis is specially prevalent among workers in the boot and shoe industry, as compared with the general population." The Registrar-General's Decennial Supplement of 1931 makes the same point in listing the mortality-rate from respiratory tuberculosis of 86 occupational groups, among which that of boot and shoe operatives was only less than that of (1) costermongers and newspaper sellers, (2) barmen, (3) glaziers, polishers, buffers, and moppers, (4) potters, ware-makers, casters, and finishers, and (5) grinders.

In 38,632 Northamptonshire examinations the number of active tuberculosis cases discovered was 4·4 per 1000, but in the boot and shoe trade the figure was 5·7 compared with 3·25 in other occupations. Up to the end of 1945 about 797,000 civilians had been examined by mass radiography in England and Wales and 3·6 per 1000 of them were diagnosed as having active pulmonary tuberculosis. In the London County Council's survey of 46,671 people, 3·1 per 1000 were found to have the disease; in Birmingham (13,700 examinations) 3·6 per 1000; and in Glasgow (30,052 examinations) 5·0 per 1000. The Medical Research Council's examination of 10,103 office workers showed that 4·0 per 1000 had active pulmonary tuberculosis; in two factories employing 4720 and 5657 workers the rates were 3·0 and 4·0 per 1000. It will be seen that Northamptonshire's pulmonary tuberculosis rate is the second highest (after Glasgow) among the surveys made.

REASONS

After establishing that the incidence of active tuberculosis was higher in the boot and shoe trade than in other Northamptonshire occupations, Smith analysed the incidence in the various occupational categories within the trade. He found that there was an excess in the clicking, lasting, and finishing departments. (Clicking consists in cutting upper leather into components; lasting in attaching the bottoms of the boots to the uppers; and finishing in trimming and polishing heels and edges.) Among 1864 clickers the expected number of active tuberculosis cases was 4·14, but the number actually found was 12; among 3282 men in the lasting department, the expected number was 7·45 and the actual 20; while among 1872 workers in the finishing department the expected number was 4·41 and the actual was 15. In all the four main areas of the county there was an excess incidence of pulmonary tuberculosis in the boot and shoe trade.

In 1915 the high incidence of pulmonary tuberculosis in boot and shoe operatives was attributed to the sedentary nature of the work and possibly to the cramped attitudes of the worker. Factors thought to favour infection were defective lighting, infected dust, inadequate ventilation, and especially the presence of infected workmates. In Smith's opinion there is no doubt of this last factor, but further investigation would be needed to show that lighting and ventilation are worse than in other industries. Reports by H.M. inspectors of factories, quoted in last year's report of the Working Party on the boot and shoe industry, describe the conditions as of a "good medium standard," though the industry is not up to date in welfare matters. The work is not especially dirty, unpleasant, or heavy, and there is no overcrowding in the legal sense, but there is considerable congestion in many shops owing to the use of boot racks. The means for promoting good general ventilation (e.g., windows and doors) are generally adequate but seldom well used. A report by one of H.M. medical inspectors speaks of a tendency to crowd as many workers and machines as possible into small rooms which too often are ill ventilated. Rather than take advantage of open windows, the workers prefer "to immure themselves in a hot air bath. . . . Clickers with whom I have spoken abhor a draught as nature abhors a vacuum. Most of them think, in the colder season at least, that it is unnatural to work with open windows at their trade. In the smaller factories visited, I observed only two instances of the windows being open during work."

Smith thinks that, before expressing an opinion on work posture in relation to tuberculosis, comparisons are required with other sedentary occupations. Other possible factors are (*a*) selective recruitment, in that many branches of the work can be done by men who are not robust; (*b*) injurious dust particles, though there is so far no evidence of a dust factor; and (*c*) economic factors, such as wage levels. Some of the factory buildings are good; others are substantial but need much internal alteration to comply with the Factories Act; and others, again, should be demolished.

INFECTION AT WORK ?

Referring in a leading article to the Northamptonshire survey and to the Working Party report the *Times* of March 20 says: "This seems to be another example of the perpetuation of a specially serious threat to health because measures proposed to meet it have been largely ignored. The blame is perhaps widely shared, but the evidence suggests some degree of administrative breakdown, central and local." It is well to remember, however, that the factors in the spread of tuberculosis are economic and social and not necessarily occupational. Undernutrition, overstrain, and poor housing conditions are well known to contribute to its onset. It is remarkable how often, when cases of tuberculosis in factories are investigated, it is found that intimate contact has occurred in the home with open cases of tuberculosis. This is not to say that cross-infection cannot take place in a badly ventilated and overcrowded factory, but there have been few proved cases.

their House, will challenge the Government on a major tter of legislation; for they do not want their powers be further limited.

A question to the Foreign Secretary revealed that en the most important reports of the United Nations e only generally available in this country after a long riod. F.A.O. reports published last autumn in ashington are not available generally even in May. far there are in this country only half a dozen copies the report on the formation of the international police rce, drawn up by the military staff committee of the nited Nations. Yet perhaps the fate of the world pends on making that international police force work d work efficiently.

MEDICUS, M.P.

FROM THE PRESS GALLERY

Our Calories

IN the House of Lords on May 22 Lord CHERWELL ointed out that it had been stated in the House of ommons by a Government spokesman that the domestic tion and the domestic entitlement of 8 points per week rovided 1600 calories a day. What food was available, e asked, to provide the extra 1300 calories a day required bring this figure up to the 2900 calories which Lord ddison said were obtainable by people who did not se restaurants and canteens. Lord Addison had complained that the figures given in Dr. Franklin Bicknell's rticle in the *Medical Press* were out by about 30% nd that the average person in Great Britain gets not 100 but 2900 calories a day. But if, as the Ministry f Food stated, only 1600 calories a day were to be erived from rationed and pointed foodstuffs, was r. Bicknell right in assessing the amount to be derived rom other sources, excluding canteen and restaurant eals, at 500 calories, or was Lord Addison right when e declared it to be 1300 calories a day from unrationed ources. According to the Ministry of Food's own ietary survey food eaten in the home was equivalent n December, 1945, to 2390 calories, and in December, 1946, to 2300 calories. That figure was nearer Dr. Bicknell's assessment of 2100 calories than Lord Addison's of 2900.

Lord Addison had also protested against the statement that unemployed before the war were better fed than most of the nation today. Lord Cherwell believed that to be broadly true. Some ten years ago Sir William Crawford and Sir John Boyd Orr had estimated the verage calorie intake of the lowest income groups at 2335 and 2317 a day respectively. Surely these igures supported Dr. Bicknell's statement.

Sir William Crawford's investigation further showed that the poorest 15% of the population got 65% more meat, 80% more bacon, 46% more fats, and 96% more sugar than the ration allowed today. A fervid vegetarian might say that the people were better fed today because they were getting less meat. But the fact that a small percentage of the population might be getting slightly more food did not outweigh the fact that the overwhelming majority were getting a great deal less. It was an abuse of language to say that the country as a whole was better fed than ever before. He was concerned with the normal man and woman, the small shopkeeper, the clerk, the adolescent, and especially the unhappy housewife, whose life of queuing and contriving left her no time for meals in restaurants and canteens. He asked the Government what were the rts and amounts of food which these people could y outside their rations and points to make up the ifference of 1300 calories.

Lord ROTHSCHILD felt that Lord Cherwell's question ast some doubt on the figure of 2900 calories per person er day as the average consumption of food in this ountry. The exact figure, he added, was 2880 calories. his figure applied to the whole population and Lord ddison, he believed, had nowhere said it applied o people who did not use restaurants. The combined nited Kingdom, United States, and Canadian Consumption Levels Enquiry Committee concluded in 942 that the method used by the Ministry of Food o obtain the figure of 2900 calories was the best method vailable and it was identical with the method used before the war to get similar data. The figure of 1600 calories obtainable from the ordinary adult ration took no account of unrationed foods, welfare food schemes, special rations for miners, extra cheese rations for some workers, the sweet ration, the consumption of food in restaurants and canteens, and the allocations of rationed foods to the manufacturers of composite foods which were unrationed to the consumer. In a letter to the *Times* Lord Cherwell had compared the calorific value of the adult rations with the pre-war average consumption of the same food by the poorest 15% of the population. The two figures were not comparable. The first was a minimum entitlement, while the second was an average total consumption. The only true comparison between now and before the war was given in the Consumption Level Enquiry Reports. The national diet had its defects and monotonies which he hoped would be rectified. But compared with pre-war levels of consumption assessed in the same way as now the deficiencies were nowhere near as great as some of the critics of the Government would have people believe. Grave as its difficulties might be this country was not dying of starvation, and the Government's figures were not lies used for political purposes.

Viscount ADDISON affirmed that the figure of 2900 calories was an overall and not an individual figure of consumption, and in the last debate when using this figure he had not mentioned people using restaurants or canteens. The comparable figure for the pre-war period was 3000 calories, a drop of 100 calories.

There was no doubt, Lord Addison admitted, that our food today was less varied, attractive, and palatable than our pre-war diet. The total consumption of meat today was about 9% less than pre-war. Fats were down by 29%, sugar by 26%, eggs by 14%. On the other hand, the consumption of dairy produce, especially milk, was up by 30%, fish by 28%, and flour (notwithstanding bread rationing) by 10%. While our diet was duller and less palatable than before the war, it approximated more and more closely to the nutritional foundation upon which it should be based—namely, dairy produce, vegetables, and high-extraction bread, rather a pedestrian diet, far removed from the æsthetic levels of an hotel grill-room.

The figure of 1600 calories was made up of the basic ration of 1400 plus the ordinary adult points ration of 200. In addition to the rationed foods there were also a number of additional sources of food, including the bonus issues of sugar and jam, meat pies, sausages, fried fish and chips, the sweet ration, vegetables, and fruit. Meals obtained in canteens and restaurants were not a minor contribution to the provision of food. There were at present 25,000 factory canteens; school canteens and canteens for young persons exceeded 29,000; there were 15,000 British Restaurants, about 3000 Service canteens, and about 92,000 commercial catering establishments. These places provided a total of nearly 180 million meals a week. Agricultural workers and others, who could not use canteens, benefited under special schemes by which they could obtain supplementary rations.

The Government naturally wished that the national diet might be more plentiful and more varied and attractive, and they looked forward to the time when changes to that end could be introduced. But the House could rest assured that the food requirements of the people as a whole were being adequately met and that there was no room for alarm and despondency. He still regarded the statement that England was dying of starvation as an absolute falsehood. Statements of that kind ought not to be made. They were sloppy, inaccurate, and mischievous.

Lord CHERWELL said the figures quoted for restaurant and canteen meals were equivalent to only 1¼ main-meals per head of the population each week. If the Government claimed that such an enormous amount of food was consumed, they should increase the ration. If the Government figures were right, they implied that some people were getting much more food than others. Lord Addison had not dealt with the fact that a normal person without access to canteen or restaurant meals obtained only 2300 calories. Lord Cherwell could not pretend he was satisfied with the Government reply. They said all diarrhœa and enteritis under two years, and 11 (3) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 270 (corresponding to a rate of 27 per thousand total births), including 41 in London.

Diary of the Week

JUNE 1 TO 7

Monday, 2nd

Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
3.45 P.M. Mr. H. F. Lunn: Integument. (Arnott demonstration.)
5 P.M. Mr. J. W. Tudor Thomas: Corneal Transplantation.
Fellowship of Postgraduate Medicine
5 P.M. (St. Stephen's Hospital, Fulham Road, S.W.10.) Dr Mervyn Gordon, F.R.S.: Is Rheumatism a Virus Disease?
Westminster Hospital Horseferry Road, S.W.1
5 P.M. (Meyerstein theatre.) Clinico-pathological demonstration on Chronic Mastitis.

Tuesday, 3rd

Royal College of Surgeons
5 P.M. Mrs. A. Pirie: Experimental Aspects of Nutrition and Eye Disease.
Fellowship of Postgraduate Medicine
5 P.M. (St. Stephen's Hospital.) Prof. B. W. Windeyer: X-ray Therapy in the Chronic Rheumatic Diseases.
London School of Dermatology, 5, Lisle Street, W.C.2
5 P.M. Dr. A. D. Porter: Diseases of the Hair.

Wednesday, 4th

Royal College of Surgeons
3.45 P.M. Mr. H. F. Lunn: Alimentary Canal. (Arnott demonstration.)
Fellowship of Postgraduate Medicine
5 P.M. (St. Stephen's Hospital.) Dr. Francis Bach: Physical Medicine Department in the Treatment of the Rheumatic Sick.
Medico-Chirurgical Society of Edinburgh
8.30 P.M. (7, Drumsheugh Gardens.) Dr. J. L. Henderson: Reflections on American Medicine.

Thursday, 5th

Royal College of Surgeons
5 P.M. Mr. R. W. Nevin: Intestinal Amœbiasis. (Hunterian lecture.)
Fellowship of Postgraduate Medicine
5 P.M. (St. Stephen's Hospital.) Dr. W. S. C. Copeman: Non-articular Rheumatism.
London School of Dermatology
5 P.M. Dr. F. R. Bettley: Seborrhœic Dermatitis.
Edinburgh Post-Graduate Board for Medicine
4.30 P.M. (Royal Infirmary.) Dr. W. Lindsay Lamb: Chronic Diarrhœa. (Honyman Gillespie lecture.)

Friday, 6th

Royal College of Surgeons
3.45 P.M. Mr. H. F. Lunn: Pelvic Girdle. (Arnott demonstration.)
5 P.M. Mr. H. Ridley: Nutrition and Eye Disease.
Fellowship of Postgraduate Medicine
5 P.M. (St. Stephen's Hospital.) Dr. Grace Batten: X-ray Diagnosis in the Chronic Rheumatic Diseases.

Births, Marriages, and Deaths

BIRTHS

Bevan.—On May 20, at Hertford, the wife of Dr. J. E. C. Bevan—a daughter.

Hebbert.—On May 22, the wife of Dr John Hebbert—a son.

Hicks.—On May 16, in London, the wife of Dr. A. C. Hicks—a son.

Mackenzie.—On May 22, at Woking, the wife of Dr. M. D. Mackenzie—a daughter.

Mann.—On May 19, in London, the wife of Dr. W. N. Mann—a son.

Robertson.—On May 18, at Morpeth, the wife of Dr. R. P. Robertson—a son.

Smith.—On April 11, in Ipswich, Dr. Katherine Vajdora, wife of Dr. L. E. Smith—a son.

MARRIAGES

Craig—Dumaresq.—On May 17, in London, James Donaldson Craig, M.B., to Joan Lucia Dumaresq.

Kingdon—Appleby.—On May 2, at Fareham, John Renorden Kingdon, M.B., to Margaret Appleby.

Lucas—McGurk.—On May 17, at Brook Green, Peter Ferrers Lucas, captain R.A.M.C., to Fionnuala Doreen McGurk.

DEATHS

Cant.—On May 22, at Woodley, near Stockport, Frederick Cant, M.R.C.S., aged 85.

Churcher.—On May 21, in London, Thomas Gillard Churcher, M.B. Edin., aged 91.

Cooper.—On May 21, at Surbiton, Harry Cooper, D.M. Oxfd.

Elliott.—On May 22, at Oundle, Arthur Forbes Elliott, M.B. Camb., aged 70.

Evans.—On May 19, David John Evans, M.B. Birm., F.R.C.S.

Kinnear.—On May 15, at Dundee, William Lindsay Kinnear, M.B.E., M.D. St. And., F.R.C.P.E.

McCall.—On May 24, at Worthing, Henry Dundas McCall, M.R.C.S.

Macnab.—On May 20, at Winchester, Allan James Macnab, C.B., C.M.G., F.R.C.S., colonel, I.M.S. retd., aged 82.

Robinson.—On May 21, at Walton-on-Thames, Oliver Long Robinson, C.B., C.M.G., M.R.C.P., major-general late R.A.M.C.

Notes and News

TREATMENT OF THE ALCOHOLIC

Alcoholics seldom present themselves for treatment, and those who come up against the police are not usually referred for medical advice; so doctors have little opportunity to intervene in such cases. Dr. S. Izikowitz[1] would change this. He suggests that persons arrested for drunkenness should not be fined or otherwise punished but should be examined and if necessary treated, and he favours the establishment in Sweden of a special hospital for this purpose. Though "aversion treatment" is in his experience better than others, he denies that any one method is reliable, and he recommends ringing the changes by what he calls "summation therapy" From Sweden, too, comes the report that intractable alcoholism has yielded to frontal lobectomy, which has been undertaken in a few cases by Dr. Gösta Rylander. Experience so far has, however, been insufficient for the merit of this serious undertaking to be assessed.

INCREASED DISABILITY ALLOWANCES

Last year the Ministers of Pensions and of National Insurance set up an interdepartmental committee to consider the pensions payable for specified injuries. The committee's recommendations[2] have been accepted in principle by the Minister of National Insurance as a basis for regulations under the National Insurance (Industrial Injuries) Act. The Minister of Pensions has also accepted the report, with effect from April 1. For the loss of the left hand or arm the pension, hitherto 10 degrees less, is now the same as for the right arm at the corresponding site; the assessment for amputation through the shoulder is increased from 80% to 90%, and for loss of four fingers from 40% to 50%. The assessment for amputation through the hip-joint is increased from 80% to 90%; and there are other minor changes These increases will be automatically applied to the allowances of those disabled in the late war; but pensioners of the 1914–18 war must apply for a review of their awards. About 7000 pensioners will benefit by the new arrangements, which will cost slightly over £100,000 a year.

TRAINING OF LOW-GRADE DEFECTIVES

Those who work with low-grade defectives know they are not the useless clods they appear to the casual visitor. Dr. E. J. Fitzgerald,[3] formerly medical superintendent of Bridge Home, Witham, Essex, notes that such patients must be systematically taught things which the normal child picks up without training; but the point is that they *can* be taught, and that they enjoy learning.

The patients at Bridge Home are adult men, less than half of whom have a mental age above five years; yet in 1946, of 363 patients (including among them 80 with epilepsy, 52 crippled or partly crippled, and 12 blind) only 7 were completely unemployed, and none were bedridden. Cripples are trained to walk in various ways: a patient, placed at one end of a pair of parallel bars, is encouraged to leave his chair and pull himself along between the bars; as his powers improve he learns to walk, pushing his chair in front of him, or wheeling large toys, home-made in the form of a steam-roller or an engine. Later he will climb a wooden slope, cross a little bridge, descend some steps, and open a gate; and all these exercises are done wher possible in the open-air. Even helpless cripples lie out-of-doors on rugs, and exercise themselves by working to captur toys placed just out of reach. Many are able to take part in physical-exercise classes, using an outdoor gymnasium set consisting of a swing, climbing-rope, and trapeze. The rest of the equipment, since it needs to be exceedingly strong, is home-made and includes a rocking-horse made from an old gymnasium horse, and a fixed bicycle arranged on rollers so that the effort required to pedal it is equivalent to that used in a ride up a slight hill. Wheelbarrows filled with sand are pushed up and down inclined planks, low hurdles are crossed, and the men play at skittles and at a simple ball game, in which balls are thrown up into baskets which correspond in colour with sashes worn by the players Set exercises only last for 15 minutes in the hour, and for the rest of the

Nevertheless Smith's findings constitute a challenge to the authorities, both central and local, to see what can be done to diminish the high incidence of tuberculosis in the boot and shoe trade. Further investigations will have to include comparisons not only of factory conditions but of the housing, nutrition, wages, and social habits of the workers in the various occupations.

Water and Health

The report of the Water Pollution Research Board,[1] ecently issued, covers the years from 1939 to 1945 and the first to deal with the experiences of the war. Preoccupation with war-time problems is obvious. nvestigations ranged from the provision of drinking-water for use in ships' lifeboats and in R.A.F. dinghies to the camouflaging of lakes and reservoirs or the evolution of a satisfactory closet for air-raid shelters. For the lifeboats a still was devised which, if operated for ten hours a day for fourteen days, could produce some 0 gallons of potable water on a consumption of some gallons of paraffin oil. For the airmen's dinghies briquettes were produced to make sea-water drinkable by treating it with silver zeolite, silver oxide, and barium chloride. The briquettes would not readily break up in sea-water; bentonite or fuller's earth was therefore added; it swelled when it became wet, and thus dissolved the compressed briquette. As for the camouflaging of bodies of water, when the Ministry of Home Security sought to make them invisible to enemy aeroplanes, experiments were made with a thin skin of oil and a layer of treated coal powder. The effect on taste, odour, and bacterial growth was not too bad; but the camouflage experts found that the coating failed to remain evenly spread in any but very calm weather.

War damage and developments at Coventry obliged the city to supplement its water-supplies by drawing from the Avon, the intake being returned as a sewage effluent further downstream. This led to an interesting study of the effect of chlorinating the sewage effluent, a practice often urged upon municipal authorities but previously little investigated. The tests suggested that continuous application of a dose of chlorine equivalent to 10 parts per million would consistently destroy nearly all of the bacteria by the end of the 3-hour period during which the effluent was passing through the humus tanks. But chlorination greatly increased the toxicity of matters like gas liquor, usually found in the sewage of towns. Fish poisoning resulted. The Coventry experiment in chlorinating effluents was discontinued, but useful work has been done in a bacteriological survey of the Avon.

Among other phenomena investigated by the Water Pollution Research Board are the nuisance from flies bred in percolating filters, and the discharge of industrial wastes—chromate from tanning, cyanide from electroplating, and other effluents from beet-sugar factories, flax retting, photographic processes, and viscose rayon works. A promising development at Birmingham shows that "alternating double filtration" may enable sewage to be dealt with at three times the rate of the older method of single filtration, the resultant effluent being substantially of the same quality. Thus smaller plant and less land are required for sewage disposal.

These examples of the topics covered by the research board's report will suffice to show its value to students of public health. Camp sites, housing sites, and factory sites were often selected in the last six years for imperative reasons of security and military advantage. The Government departments concerned had the wisdom to ask the advice of the Water Pollution Research Laboratory where helpful data and experience were accumulated. Today, with new towns being planned and new industries introduced, and with rural water-supplies and sewerage being provided and improved under the Act of 1944, the opportunity of consultation must not be forgotten.

Diphtheria Immunisation

The annual return on diphtheria immunisation by local authorities is made on forms provided by the Ministry of Health, which asks the M.O.H. to amplify the information by giving, on an additional form (appendix to circular 62/47), particulars relating to each death from diphtheria in an immunised child. Facts now required include not only the dates of primary immunisation, and of any reinforcing dose given, but also the date when the child was first seen by the doctor and the date on which antitoxin was administered.

Smallpox

Contacts are still under surveillance in connexion with foci of infection at Barnsley and Sheffield, Yorkshire, and at Bilston and Coseley, Staffordshire.

Barnsley.—The source of infection has not yet been determined with certainty, but a man who had been exposed to smallpox in a common lodging-house at Scunthorpe, and at the time was revaccinated successfully (on April 5), arrived at the Barnsley lodging-house (24a, Doncaster Road) on the evening of April 30. Among innumerable marks of acne, scabies, and trauma on his body were one pock-mark, suggestive of variola six or more weeks before, and half a dozen nondescript scars which might have been modified smallpox. Attempts to culture variola virus from him have failed. He has been notified as smallpox and is in hospital.

In addition to the man removed from Bermondsey on May 16 there are now 5 cases in the first generation arising at Barnsley. Of these, 3 were mentioned last week; the other 2, men aged 68 and 70, developed rashes on May 17 and 19. It is doubtful whether the man from Scunthorpe could have infected the earliest case in this generation, who is recorded as having had a pustulo-vesicular rash on admission to a general ward at St. Helen's Hospital, Barnsley, on May 13, where he remained until removed to a smallpox hospital on May 16.

There were 93 men, women, and children sleeping in the Barnsley lodging-house when the disease was detected there on May 16. Of these, 5 absconded, but only 2 (Elizabeth Fenton and Lewis Stewart) remain untraced. Assuming that the period of infection at Barnsley commenced about April 26, several contacts who left 24a, Doncaster Road before surveillance commenced are still untraced. They include the following persons:

Stanley Arnold, William Barker, William Boyce, John Brooks, John Byrne, Elizabeth Cassidy, John Cassidy, Edward Cragan, James Cummins, John Dean, Margaret Dean, Pat Duffrey, George Foster, Mr. and Mrs. Gee, John Hardy, Andrew Henry, Albert Jeffrey, Martin Kearney, James Kennedy, Frank King, Joseph McFeahin, Michael McNamara, John Nylard, Florrie Payne, Albert Pickersgill, Charles Pocklington, Clifford Stringer, John Underwood, Jacob Warren, William Weir, James White, Walter Wright, and Thomas Durkin. The last-named slept at 24a, Doncaster Road on April 27 and 28.

A man named Thomas Durkin was a contact with smallpox at Grimsby. Any news concerning his whereabouts should be communicated immediately to Whitehall 4300, extension 145.

The disease at Barnsley is variola major of a severe type; 2 of the patients have died.

Sheffield.—The father and aunt of the original case have been removed to hospital. The father, successfully vaccinated for the first time on May 5, sickened on May 13, and developed a markedly modified smallpox rash on May 18. The aunt is at present a suspect only.

Bilston.—A new case has been removed to hospital. The patient is an unvaccinated child, aged 11, with onset on May 16 and rash on May 19. She lived in a house near that of cases removed in April.

Coseley.—An unvaccinated kitchen-maid at Moxley Infectious Disease Hospital became ill while living at home in Coseley on May 13. A severe confluent eruption appeared on May 15.

Infectious Disease in England and Wales

WEEK ENDED MAY 17

Notifications.—Smallpox, 12; scarlet fever, 1028; whooping-cough, 2120; diphtheria, 243; paratyphoid, 3; typhoid, 9; measles (excluding rubella), 12,678; pneumonia (primary or influenzal), 578; cerebrospinal fever, 57; poliomyelitis, 11; polioencephalitis, 0; encephalitis lethargica, 2; dysentery, 65; puerperal pyrexia, 139; ophthalmia neonatorum, 85. No case of cholera, plague, or typhus was notified during the week.

Of the 12 cases of smallpox, 6 were notified at Barnsley, 4 at Bilston, Staffs, and 1 each at Birmingham and Bermondsey, London.

Deaths.—In 126 great towns there were no deaths from enteric fever, scarlet fever, or diphtheria, 8 (0) from measles, 11 (1) from whooping-cough, 80 (7) from on August 15, 1945, the troubles of this unhappy region seemed to be at an end; but in the civil strife which followed, lawlessness and disorder gained ground, terrorists robbed and tortured two members of the hospital staff, the chief clerk of the hospital was enticed from his house and shot, and all were working in danger and uncertainty. Nevertheless the work went ahead, and over 700 cases of gunshot wounds were treated. By spring of last year supplies were exhausted and the staff worn out; but from that time things have improved; help has come from all sides—from the British Red Cross, from friends in China and Canada, from CNRRA and UNRRA. Old staff are returning, and the work is ready to grow again.

---

[1] Water Pollution Research 1939–45. Report to Department of Scientific and Industrial Research. H.M. Stationery Office. Pp. 78. 1s 3d.

Being a mission hospital, Moukden has received no outside help since 1941, and has had, all that time, to support the medical college. Now dormitories and lecture rooms are needed for nurses, new surgical instruments and nursing supplies, and a new children's ward. UNRRA-CNRRA have promised £5000, but at least £15,000 more is needed. Those wishing to help should write to the Rev. J. C. Dorward, Secretary of the Moukden Medical College, at F.M.C. Offices, Church of Scotland, 121, George Street, Edinburgh, 2.

University of Cambridge

Sir Lionel Whitby, regius professor of physic in the university, has been elected master of Downing College.

University of Leeds

On July 16 the honorary degree of doctor of philosophy is to be conferred on Mr. H. A. Mahony, L.D.S., principal dental officer of the Ministry of Health, and Mr. W. G. Senior, L.D.S., secretary of the British Dental Association.

University of Birmingham

In collaboration with the city public-health department, the pædiatric department of the university is establishing a breast-milk bank. Until a suitable building can be erected the bank will be housed at the Children's Hospital.

Messrs. Cow & Gate have endowed several scholarships to be tenable at the Children's Hospital and at the Children's Institute. One is to be awarded for psychiatric work in connexion with the follow-up of premature babies.

University of Belfast

The minister of health for Northern Ireland has announced that a chair of social and preventive medicine is to be set up at the Queen's University.

University of St. Andrews

To mark the visit by the British Association for the Advancement of Science to Dundee, the honorary degree of LL.D. will be conferred on August 29 on Sir Henry Dale, O.M., and Sir Alexander Fleming, F.R.S.

Royal College of Surgeons of England

The American College of Surgeons have made a further gift to the restoration of the college, bringing their total contribution to over £10,000. Of the £250,000 required for the restoration of the college £176,000 has now been collected. The American college is also giving a desk and lectern for the lecture theatre of the English college, which will be formally presented by one of the members of the board of regents during the congress of the International Society of Surgery to be held in London next September.

Royal Society of Arts

The Albert medal of the society has been awarded this year to Sir Robert Robinson, D.SC., P.R.S., Waynflete professor of chemistry in the University of Oxford, for his contributions to the advancement of organic chemistry.

Middlesex Hospital

Sir Jack Drummond, D.SC., F.R.S., will deliver the Sanderson-Wells lecture for 1947 at the Middlesex Hospital at 4.30 P.M. on Tuesday, June 24, when he will speak on the Nutritional Value of Bread. The lecture is open to all members of the medical profession.

Association of Orthopædic Physiotherapists

At a meeting of the association to be held on Saturday, June 7, at 2.30 P.M., at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1, Brigadier R. J. Furlong, F.R.C.S., will speak on the Spine and its Physical Treatment.

Congress on Urology

The International Society of Urology is holding a conference at St. Moritz, Switzerland, from August 25 to 28. The subjects chosen for discussion are Ætiology of Primary Renal Calculus, Renal Tuberculosis, Transplantation of the Ureter, Use of Sulphonamides and Penicillin in Urology, Hormone Therapy in Cancer of the Prostate. The speakers will include Mr. H. P. Winsbury-White, Mr. Hamilton Bailey, Dr. Cuthbert Dukes, Mr. David Band, Mr. Arthur Jacobs, Mr. Yates Bell, and Mr. Clifford Morson. Further particulars may be had from Mr. Morson at 86, Brook Street, London, W.1.

Congress on Mental Health

An international congress on mental health will be held at the Central Hall, Westminster, from August 12 to 21, consisting of the following conferences: child psychiatry (12th–15th); medical psychotherapy (12th–15th); mental hygiene (16th–21st). The themes of the three conferences will be Foundations of Mental Health in Childhood, Guilt, and Mental Health and World Citizenship. The National Association for Mental Health is making arrangements for the congress, and further information may be had from the organiser, 39, Queen Anne Street, London, W.1.

International Chemical Congress

The eleventh International Congress of Pure and Applied Chemistry will be held in London from July 17 to 24 under the presidency of Lord Leverhulme. The 14 sections will include: biochemistry (chairman, Prof. A. C. Chibnall, F.R.S.); chemistry in relation to food and nutrition (chairman, Sir Jack Drummond, F.R.S.); and chemistry in relation to medicine and therapeutics (chairman, Prof. C. R. Harington, F.R.S.). During the congress lectures will be given by Sir Henry Dale, O.M., and Sir Robert Robinson, P.R.S. Further information may be had from the press officers of the congress, 11, Garrick Street, London, W.C.2.

Chelsea Clinical Society

Proposing the toast of The Society at the jubilee dinner held at the South Kensington Hotel on May 20, the Earl of Clarendon, Lord Chamberlain, said that fifty years ago 15 medical men began meeting once a month in a Chelsea dispensary. In 1922 dinner meetings were started, and by 1938 the society had 230 members. Lapsing in the war, it was revived in 1945, with the same invaluable spirit of intimacy and fellowship. Dr. Ronald Jarman, the president, who said that the membership is now 214, described the society as a happy family, and spoke of the part played by Mr. Paxton Baylis, Dr. Harriott Coke, and Dr. Kenneth Eckenstein in its restoration. Sir Cecil Wakeley, proposing The Guests, resolved any existing doubts about the tenure of office of the presidents of the three Royal Colleges: for the Physicians, he said, it is 7, 14, or 21 years; for the Surgeons, 7 years; and for the Obstetricians and Gynæcologists, 9 months. Mr. Russell Vick, K.C., replying lightheartedly and gratefully for the visitors, produced a new adage for these latter days: "You've got to take the rough with the rough." Sir Hugh Lett, president of the British Medical Association, said that the society kept its proceedings on a high level both of professional interest and of friendship and social activities. In future medicine would have to encourage such activities. There were those who wanted to see every doctor not only a servant of the State but a member of a trade-union; but the voice of the people was a variable and incalculable thing, and if the people were making a serious mistake we should do our best to persuade them to change their minds. This could only be done if members of the profession talked things over and reached their own conclusions as to what is right, and the closer the association between doctors the better it would ultimately be for the community.

Major-General Sir Colin Gubbins testified to the help given by doctors during the war in the organisation of resistance movements. At the end of the dinner Dr. Jarman handed over the presidential badge to Dr. W. N. Maclay.

Appointments

BAINES, G. H., M.B. Camb., F.R.C.S.: surgeon to outpatients, Children's Hospital, Birmingham.

CAIRNS, J. G., M.D. Edin., D.P.H.: clinical tuberculosis officer, Cornwall.

HAWKINS, L. A., M.B. Camb., M.R.C.P., D.C.H.: physician, Doncaster Royal Infirmary.

RAFFAN, A. W., M.B. Aberd., D.A.: asst. anæsthetist, Royal Aberdeen Hospital for Sick Children.

time the patients amuse themselves by free play with any of the apparatus which takes their fancy. Habit-training is associated with rewards, including a penny a week for sweets.

A sensory-training and occupational class is held in a pavilion. The patients begin by playing with peg-boards, nests of cubes, sets of buttons and buttonholes, and picture puzzles; later they are systematically taught kindergarten occupations, and finally they learn to knit dishcloths, or make wool-mats and paper-bags. In a manual instruction class they do simple repairs, help to fill mattresses, clean shoes and knives, and make up bundles of wood. As far as possible anyone who has been at a sedentary class in the morning goes to a physical-exercise class in the afternoon, and all are encouraged to attempt simple household tasks and personal care. They are also encouraged to feed themselves, even if they are clumsy and untidy about it. Many of the lower-grade patients are able to take part in the percussion bands, which, accompanied by a gramophone and conducted by one of the male nurses who has served in an Army band, gives pleasure to both performing and listening patients.

Good results of this programme of training and occupation are apparent not only among the patients: as Dr. T. B. Jones, the present medical superintendent, points out in a final note to Dr. Fitzgerald's article, "nothing can be so dull as the duty of caring for low-grade patients if they are left to sit about unoccupied. A training scheme gives the staff additional interest which is very real and satisfying."

CONQUEST OF PAIN

Using a simple conversational style, and without probing too deeply, Mr. Bankoff[1] gives an epitome of the chequered history of man's struggle to abolish pain. He writes in a manner calculated to help the lay reader to realise with what faltering steps anæsthetics have reached their present state. It is difficult indeed to believe that it was not until about a hundred years ago that general anæsthesia was born. The primitive efforts of man to relieve pain are lightly touched upon, especially in relation to surgery. Hippocrates was the first to separate medicine from religion, and Mr. Bankoff presents his work in the form of a Socratic dialogue between Hippocrates and his pupil Teucer. But lofty as was his teaching and practice as a physician, Hippocrates got no nearer a solution of the eternal problem of pain, and for centuries mankind continued to suffer the pain of disease and at the hands of the surgeon. It is a remarkable fact that the pioneers of most human advances have had to withstand persecution, mentally and physically and often at the hands of the mob. And so it was in this case: priests were often foremost in their efforts to frustrate attempts to lessen human suffering, and so were many doctors. The grim story of the horrors of surgery up to the early 19th century will help readers of this book to appreciate more fully the boon conferred on us all by the discovery of general anæsthesia.

JEROME CARDAN

In his monograph on Cardan we are indebted to Mr. Eckman[2] not only for a praiseworthy effort to present fairly and temperately the career of one of the most contentious figures in medicine, but also for bringing vividly before us the great resurgence of medicine and science during perhaps the most glorious period of the Renaissance. He recalls many of the great names of those who lived at that time and whose work has come down to us as a priceless heritage. Amid such surroundings, Jerome Cardan lived and worked. Eckman's notes and references show how thorough his investigation has been, and at the same time how difficult it is for us at this period of history to distinguish the genuine seeker after truth from the charlatan. Cardan is in fact a psychological riddle. His personal and family history from childhood onwards was unhappy, and no doubt left its mark upon his later life which was one of storm and stress, indicating at least a certain instability of mind and character. He was disputatious and vainglorious, and apparently had a faculty for making enemies; and in his work he did not seem to scorn the charge of plagiarism. Eckman endeavours to place fairly before us his contributions to medicine and science, condoning nothing unworthy, but at the same time showing us that, either from malice or ignorance, his critics have traduced him. Cardan's belief in astrology and the occult were held against him, but indeed this was shared by many distinguished men of his day now held in high esteem by the scientific world. Did not Sir Thomas Browne himself believe in witchcraft?

ANÆSTHETISTS' SALARIES IN MIDDLESEX

The salary scale for hospital staff adopted by the Middlesex County Council in July, 1945 (*Lancet*, 1945, ii, 717) has now been adjusted to bring anæsthetists more closely in line with other senior clinicians. The original rate of £1000–£50–£1400 was criticised by the Association of Anæsthetists (*Lancet*, 1945, ii, 796). The amended scale rises from £1000 by £100 to £1600 per annum and thereafter on proof of outstanding achievement by further increments of £50 to £1800.

GOVERNMENT COMMITTEE ON RESEARCH

As a sequel to the Clapham report the Government has appointed a standing interdepartmental committee on social and economic research under the chairmanship of Mr. George North, LL.D., the registrar-general. The committee will "survey and advise upon research work in Government departments, and in particular (*a*) will bring to the notice of departments the potential value for research purposes of the material which they collect and will suggest new methods and areas of collection; and (*b*) will advise on how there could be made available to research-workers information gathered for their own purposes by the departments which has potential value as material for research. The members include Dr. G. A. Clark, of the Ministry of Health, and the secretary is Mr. L. M. Feery, North-East Wing, Somerset House, W.C.2.

HOSPITAL ATMOSPHERE

A broadsheet[1] called "Humanise the Hospitals," issued by the health advisory committee of the Communist Party, says nothing new but much to the point. It remarks that something more is needed than new buildings. Many people still fear and shun hospitals in a way that hinders them from benefiting fully from the services offered there. Much of their distaste could be overcome by more kindly and considerate reception of the patient at the hands of someone trained to reassure and direct him, by more privacy during treatment, by a proper appointments system, and by a more homely and intimate atmosphere in the wards.

The committee also put a strong case for better conditions for nurses, and for wider use of part-time nurses; and they make it clear that they think many "unhappy nursing practices," including the custom of rousing patients for washing in the small hours, are due to the widespread refusal of hospitals to adopt the eight-hour shift. The domestic staff are equally deserving of better conditions of work. Doctors are criticised for not taking the patient into their confidence and discussing his case with him, and it is suggested that patients and their relatives should be allowed to see senior consultants in private at arranged consulting-hours. General practitioners should be encouraged to visit their patients in hospital.

Hospital food still gives little general satisfaction, and the committee suggest that a book should be provided for patients' complaints on this and other topics, and that these should be dealt with by a patients' ward committee on which the almoner should sit. The broadsheet ends by reminding the public that the hospitals now belong to them: they must see to it that a more human atmosphere develops.

ADVENTURES AT MOUKDEN

The Moukden Hospital, in Manchuria, founded by Dr. Dugald Christie in 1883, had its beginnings in an old three-roomed house. Nowadays it has 11 departments, 52 wards, 6 theatres, 339 beds, and 2 laboratories, and is staffed by 42 doctors, 107 nurses, and 30 dispensers. When war broke out in the Pacific at the end of 1941, all foreign workers—eight of them British and one Danish—were interned, and their duties fell on the remaining staff. The medical college was supervised by the Japanese, but the hospital was allowed to go on working as a private institution; and in 1943 the nine mission hospitals of the Manchurian Church were brought under the supervision of Moukden. Despite these heavy responsibilities and the scarcity of supplies, the staff maintained the hospital well, the nurses especially doing fine work. In 1945 the suspicions of the bogus government led them to take over the hospital, dismiss the superintendent, and suppress Christian teaching in the wards; but this bad period lasted for only four months. With the end of the war

forward towards determining the biochemical and biophysical abnormalities which underlie the disease. Epilepsy today presents an increasingly hopeful field for research.

THE FAMILIAL FACTOR

The knowledge that epilepsy tends to run in families adds to the impulse for concealment that often has so strong a hold on epileptics and their relatives. The desire at all costs to avoid having a fit in public has led in many cases to a life of limitation and confinement. Cut off from most normal social contacts, surrounded by a wall of equivocations and misrepresentations, if not of actual falsehood, the unfortunate patient is in effect treated with cruelty by those whose sole wish is to afford him affectionate protection. Short of limitations of this type, the presence of the epileptic in the family often introduces that slightly uneasy feeling into the social relationships of the rest of the family with the outside world, an uneasy feeling that suddenly springs into prominence when the possibility of marriage arises.

The social handicap arising from the familial tendency to epilepsy cannot, perhaps, be removed, but it can be lightened by facing the facts frankly. In many cases there is no more reason for concealment or for anxiety than in families one of whose members has diabetes or tuberculosis. Light on the marriage problem, either for the epileptic or for his relatives, is being thrown by the electro-encephalograph. Near relations of declared epileptics show dysrhythmia of an epileptic type five times more often than a control group from the general population (Lennox et al. 1940). This dysrhythmia may rarely be of a type that shows that they are in fact potential epileptics, in which case the routine use of a small daily dose of some anticonvulsant drug should be considered. More often there is irregular slow-wave activity of a type that suggests the likelihood of their being potential transmitters of epilepsy. Here, as in the case of the epileptic himself, an electro-encephalographic record of the prospective spouse may be of immense value. Should this be normal, the chance of epileptic offspring is small—it is perhaps unwise to give any figure at the moment, as data are insufficient. Should, however, it show the same type of dysrhythmia, the outlook for any children of the marriage would be black indeed.

Where the patient's attacks started late in life, and his mentality is up to normal, the inheritance factor is unlikely to be potent (Lennox 1945).

Finally, it must always be remembered that in many epileptics whose fits are due to local brain disease or trauma there is no evidence whatever of a familial tendency.

THE FIT: A DRAMATIC AND UNPLEASANT PHENOMENON

That epileptic fits often come unheralded with dramatic suddenness, and that, in the major form, they are often very unpleasant to witness, cannot be denied. We may view our brother epileptic with good will, but we would rather view him at a distance. Employers, shy of giving work to epileptics, often emphasise the distress that the fits cause to other employees. School-children dislike sitting next to a boy who at any time may give a loud cry, fall on the floor with a thud, and go off into convulsions from which he will emerge with a strong smell of urine on his trousers. The æsthetic shock of major fits is, in the eyes of some people, one that the general public should not be expected to put up with, and the patients should be confined to special institutions. The social corollary of all this is only too obvious. At work or at play, in school or entertainment hall, the epileptic is not wanted, and the effect on his mental outlook and his position in society needs no elaboration.

This attitude to epileptics, which ends up with something like social ostracism, can and must be fought. Surely the long years of the blitz, during which old and young, phlegmatic and sensitive, had to up to strains and horrors almost beyond ima have taught us that human susceptibility to sh less than we had thought, and can be overcome if minds are set in the right direction. Very rarely need a fit cause any alarm; and, if only we could people not to make a fuss and to take the fits in stride, much social suffering would be avoided. who crowd round and call for doctors, ambulances, brandy are unwittingly being unkind to the pa patient and to epileptics in general. True kindness i ignore the fit as far as possible. This lesson must learnt, and it can usually be taught better by employer, the foreman, or the class teacher than by doctor.

EMPLOYABILITY AND EMPLOYMENT

Some of the causes of the heavy social han of epileptics have been indicated, and suggestions that might lead to their diminution or removal. important and debatable question of employment arises. The extreme view that epileptics as a class unemployable still has its partisans, but obviously matter is one for individual assessment, and each merits careful consideration. It is a disservice epileptics generally to recommend an epileptic for if his handicaps are so severe that there is little or hope that he will retain it, for his failure will block market for his fellows. The patient's intellige attainment, aptitudes, interests, and record of p employment all come into the picture, and some atte should be made, by interview with the patient, discover any defects of temperament. Informat about temperament is better obtained from those w whom the patient lives, who should also be asked to check his own statement about his fits. It is most important to know the number of these, their regularity, their severity, their duration, the rapidity of recovery, the presence or absence of adequate warning, and the time at which they most often occur; for all these factors may have a determining influence on employ ability and the type of employment. Thus there is a large group of epileptics who only have attacks at night or at or about the time that they get up in the morning and for them the employment handicap is negligible or very small. Others have a monthly or even longe rhythm, with fits spread over two or three days and long clear periods; and here the handicap can b measured. Patients who suffer from slight petit-ma attacks in smaller or larger numbers, with transient los of consciousness but no fall, are fit for some forms o work but not for others. A warning long enough to allow the patient to assume a position of safety is a obvious asset. Rate of recovery after a fit will be a factor of importance to the employer. Frequent majo fits, occurring at any time without warning, will pu the patient outside the ordinary employment market.

Lennox and Cobb (1942), in a survey of 1000 epileptic of employment age and outside institutions who wer being treated privately or at clinics—i.e., they were al receiving medical attention—found them at work in almost every sphere, from professional or major busines situations down through skilled trades to simple labourin and domestic jobs. They record that of the total about 10% had deficient muscular strength or control (myoclonus, incoördination, weakness, or paralysis), 30% had some degree of mental retardation or deterioration, and 10–15% abnormalities of personality. There is considerable overlap in these figures, and Lennox and Cobb conclude that, taking these handicaps into consideration with that arising from frequent or severe fits, probably 25% of the 1000 were not fit for employment in the ordinary way.

SOCIAL ASPECTS OF EPILEPSY

J. Tylor Fox
M.D.Camb., D.P.M.
LATE MEDICAL SUPERINTENDENT, LINGFIELD EPILEPTIC COLONY, SURREY

The maxim that the patient must be treated as well as the disease from which he suffers is an old one, but it cannot be repeated *too often. Especially is this the* case just now when a flood of new remedies is impressing us with our ability to control infective and other disorders by chemical means.

During the last few years we have had a dramatic demonstration of the value of the combination of social with medical treatment. The urgent need for manpower led the Government to cast a questioning eye on the physically handicapped who were apparently able to contribute little or nothing to the common cause. To knowledge of medicine was added that of industrial need and opportunity, science was supplemented by good will, and encouragement combined with training; as a result tens of thousands of handicapped men and women were converted from passengers to active participators, reaching, many of them for the first time in their lives, the full status of citizenship as wage-earners. Little imagination is needed to grasp the significance of this for the men's well-being and self-esteem, for the happiness of the homes from which they came, and for the national economy in time of need. It was one of the heartening constructive accomplishments of a dark period of destruction.

The moral for us is obvious. Faced with a patient who suffers from chronic disease or disability, we shall be doing less than our duty unless we ensure that by modifying his outlook and his environment in the right directions we can enable him to take his place in the community as a wage-earning citizen, or as near that place as his handicap allows. But all this will mean a much more extended knowledge of our patient. Past medical history and present physical signs will only be the beginning. We must know something of his intelligence, his temperament, and his general mental outlook, of his educational attainment and his employment record, of the physical and emotional conditions in his home. Most doctors have neither the time nor the facilities for obtaining this information, and we must face the fact that for the adequate treatment of chronic disability, and of the social handicap that chronic disability brings with it, the doctor will have to be one of a team.

CAUSES OF THE SOCIAL HANDICAP IN EPILEPSY: THE ASSOCIATION WITH MENTAL ABNORMALITY

Especially is this true of epilepsy, where the social handicap is out of all proportion to the size and quality of the physical disorder. What are the causes of this altogether disproportionate social handicap? First and foremost is the unhappy association in the public mind of epilepsy with mental disorder, and the all too common belief that no epileptic can be quite normal. Now it is true that there are over 10,000 epileptics in the mental hospitals of this country, and probably rather less than half that number *in certified institutions for mental* defectives. Epileptic insanity may simulate any of the recognised clinical psychoses, but most of the epileptics in asylums are suffering from progressive dementia. The relationship of epilepsy and mental defect varies. Fits are a common accompaniment of the lower grades of primary amentia, while mental retardation may appear early as the result of epileptic fits in early life. Or again, both the mental deficiency and the fits may be expressions of cerebral lesions, whether traumatic, inflammatory, or vascular in origin. In any case, it is clear that the incidence of insanity and mental defect is considerably greater among epileptics than in the population generally.

Short of certifiable disorder, epileptics are believed to possess a temperament which makes them difficult to live with, to be antisocial, even to be potential criminals. A specific epileptic temperament has indeed been described, with egocentricity and hypersensitiveness as its basic characteristics; whence come unsociability, moodiness, unreliability, sudden gusts of bad temper, leading on to antisocial acts and even crimes of violence. That this picture fits some epileptics is true, as indeed it does a good many people who are not epileptic, but to apply it to epileptics generally is a grave and tragic error. I doubt if one in ten of epileptics living outside institutions possesses the epileptic temperament in any discernible degree, and the number would be much smaller but for the heavy social handicap under which epileptics exist. For, though the temperament is in some cases part and parcel of the disease, and, like fits, a manifestation of the paroxysmal dysrhythmia of cerebral cells, in many cases it is but a secondary phenomenon, the outcome of the social frustration which has dogged the patient's life from his youth up.

At a conservative estimate we may assume that there are in this country at least 100,000 epileptics outside institutions. A few of these have a severe social handicap in the form of an awkward temperament, no doubt some are mentally retarded, and a few in a prepsychotic stage, but the mental condition of the great majority is within normal limits, and many are men and women of exceptional intelligence and ability. But the almost universal belief in the close association between epilepsy and mental abnormality hangs like a cloud over the lives of them all.

THE GLOOMY PROGNOSIS

"Once an epileptic, always an epileptic." A clear diagnosis of epilepsy is almost equivalent to a life sentence in the minds of most people. Even doctors, unfortunately, often adopt this gloomy view. "There is no cure for this disease" is the medical verdict often brought along by sorrowing parents on their child's admission to a residential school; a verdict occasionally fortified by the rider "and anyhow no medicine will do him any good." Still worse is the belief that mental deterioration is the ultimate fate of every epileptic.

All this gloom is most emphatically unjustified. Very many people have repeated epileptic fits for a period during childhood and adolescence, and then the attacks disappear and do not recur. This applies, of course, particularly to cases of pure petit mal, but is far from unknown among those who have major fits as well. Naturally these people do not go about advertising their past medical history. Moreover the control and arrest of attacks by medication is becoming more effective every year. Given time, patience, and perseverance on the part of the doctor, and coöperation on the part of the patient, a drug, or combination of drugs, with optimum dosage and timing, can be worked out with resultant effective control in a surprisingly large number of cases. Mental deterioration, again, may be typical of chronic institutionalised patients who have had large numbers *of fits for many years*, but most epileptics living in the community show *no signs of it*.

There is justification for optimism about therapy in epilepsy at the present time. New anticonvulsant remedies are on their way to us across the Atlantic. And now we have the electro-encephalograph. Apart from enabling us to select cases suitable for neurosurgical investigation and treatment, it may be said that this has little therapeutic value at present, but the demonstration of cerebral dysrhythmia in its varied forms, its origin, and its mode of spread is surely a dramatic step campaign. About epileptics it may indeed be said that only knowledge of the truth will make them free.

INFECTIVE JAUNDICE IN ICELAND

L. S. Anderson
B.Sc. Edin., M.B. Manc., D.P.H.

From the Department of Public Health and Social Medicine, University of Edinburgh

The following observations are made on nineteen outbreaks of infective jaundice in Iceland between 1929 and 1940, involving 854 cases.

Iceland is a country rather larger than Ireland, three-fifths desert and glacier, with a population in 1930 of about 110,000. Its intercourse with the outside world has never been very great, and there has been little immigration to or emigration from the country, so that its particular interest therefore lies in the fact that it is a small closed community whose stock has remained unaltered for about a thousand years.

The climate tends to be dry, with more or less constant high winds, which raise clouds of fine floury dust near any centre of population. Hard frosts in winter render flush sanitation systems difficult to maintain except in the most modern installations.

The social and economic field is not easy to describe in brief; but, at the risk of over-simplification, one can divide the population roughly into three numerically equal groups: fishing, farming, and professional and administrative (*Hagskyrslur Islands*, 1926, 1937).

The fishing community is mainly compressed into small groups scattered round the coast; hence its people tend to live closely packed together. The industry is largely seasonal; in summer the herring season is in full swing on the north and east coasts, attracting many people from the south to take part. So great is the northward migration of the coastal folk in summer that the populations of some of the fishing villages may treble themselves during the season, leading to violent overcrowding. The herring season ends in early November, and soon pack-ice may render the north and east coasts dangerous, but in the south and west the cod and white-fishing continues through the winter.

The farming community, on the other hand, is very widely diffused—so widely that in winter families may be isolated for several months from contact either with other farms or with the villages, and a visitor from another district is an event of some note. In summer most of the farmers employ casual labour, often from far away, to help with the hay-making, on which the maintenance of their stock through the winter will depend, and, later, for the sheep-gathering and slaughtering in September, of which the subsequent sale represents their main and often only source of cash return.

It is difficult in a country like Iceland to draw a distinction between urban and rural populations which would be comparable with a similar distinction drawn in Britain, because, where the largest town is only the size of Falkirk or Ramsgate, it can hardly be said that there is a real urban population, but for the purposes of the present study it seems reasonable to divide the population broadly into those people, on the one hand, who live in the two main towns, are likely to spend most of their days in and round buildings with no great walking distances between, and who work with others in stuffy centrally heated rooms, but whose water and services are relatively up to date, and, on the other those who live in distinctly rural surroundings. In paper the people of Reykjavik and Akureyri have taken as "urban" and the remainder as "rural." relative populations are shown in the table.

The population of Iceland has increased very rap having doubled itself in the last hundred years, increased by 57% in the forty years up to 1930 (Jon 1940). Pari passu there has been an urban tren for, whereas in 1910 the two towns held 15% of t population, in 1930 they held 29%, and that this is n due to a higher urban birth-rate is shown by the f that in 1910 two-thirds of the people in Reykjav and even in 1930 over one-half, had been born in rural areas.

Owing to Iceland having been a democracy fo millennium, wealth and poverty are fairly evenly tributed, and the democratic habits of the people reflected in their tendency to overcrowd the liv and sleeping-rooms of their small houses. There few or no *social* barriers.

INCUBATION PERIOD

It can readily be seen that, whereas movement contact between members of the fishing communi tend to be fairly free, similar contacts among the farm folk are very much fewer; and the key to the spread infective jaundice in their case appears to be the itiner casual workers already mentioned. Hence the obser tions of the rural doctors (*Heilbrigdiskyrslur Islan* regarding the length of time which elapsed between movements of strangers known to be contacts and

A rather more hopeful picture is presented to us by the Ministry of Labour in this country. On August 19, 1946, the names of about 7500 epileptics appeared on the register of disabled persons, and of these no less than 5150 were actually in jobs on that date. This is only a partial picture; there are probably many thousands more at work who have declined to register. Many of these will be slighter cases, who have concealed their complaint. On the other side the number out of work, about 1350 or 18% of those who have registered, indicates a brighter state of affairs than actually exists. Of those in work probably a fair percentage only hold temporary jobs; and, in any case, if and when the labour demand lessens, epileptics will be among the first to go. There must, moreover, be a large number, especially of the more severe type with mental retardation, who through ignorance, laziness, scepticism, or hostility have not registered. It further appears that the disablement and resettlement officers (D.R.O.'s) of the Ministry are finding great difficulty in placing those who want work, and estimate that about half of them are so severely handicapped that they are not fit for open employment but should be placed in "sheltered workshops."

Certain types of work must be ruled out for people liable to fits, the chief of them being work with moving vehicles or live machinery, and work involving climbing ladders. There are no doubt other jobs unsuitable for epileptics, but positions of employment without risk should easily be found in any large factory or workshop.

The approach to the prospective employer should be frank; concealment can never form part of medical advice. The recommendation should be made that those with whom the employee will work be informed that he is liable to *occasional* fits, but that these need cause no alarm, and that only one man, detailed to give him the necessary minimum attention, need stop work when a fit occurs. For it is not the loss of the patient's time occasioned by a fit that worries employers so much as the general loss of time in the room in which the fit occurs. The advantages of employing a small group of epileptics, rather than an individual epileptic, might well be put to the large employer; and hesitant employers may be encouraged by the fact that many epileptics, aware of their handicap, are most anxious to do their best, and make excellent workmen.

Regular work is good for us all, including epileptics, but occupation and interest are also direct anticonvulsants. This has long been a matter of clinical observation by those who have the opportunity to watch their patients closely. We now know that carbonic and lactic acid and other products of cerebral and muscular metabolism are direct inhibitors of fits, and indeed the inhibition by mental alertness of the petit-mal type of dysrhythmia can be effectively demonstrated on the electro-encephalograph. Work in which he is interested is exceptionally good therapy for the epileptic.

For those whose handicap is severe enough to exclude them from ordinary employment, sheltered workshops, set up under the provisions of the Disabled Persons (Employment) Act, will now be an alternative to institutional treatment. The Disabled Persons Employment Corporation has already opened three of these, and plans for 50 have been approved by the Ministry (Ministry of Labour 1946). The suggestion that there should be an epileptic bay in each of these factories has now been carried into effect in one of them, and is reported to be working satisfactorily. To cover the whole epileptic population, either residential hostels in the neighbourhood of these factories, or facilities for providing work at home, would be required.

COMMUNITY CARE

The task of finding employment for epileptics, besides other disabled persons, now falls on the D.R.O.'s, who will need a working knowledge of medicine and surgery if they are to function effectively. The individual assessment of each case of epilepsy will be a formidable problem; but, unless this can be made and every case dealt with on its own merits, epileptics will be in danger of being lumped together as impossible. To assist in the original assessment, and to provide a follow-up service, a third party is needed—the trained social worker. Finding suitable employment is not going to be easy, but for many epileptics mere work-finding will not be enough. Long periods of unemployment and frustration, awkward dispositions, and mental dullness mean easy discouragement and poor powers of adaptation. Talks to the patient and his friends at home, and visits to the prospective employer, the actual employer, and the patient at work will just make the difference between success and failure, and for all this sympathy, understanding, experience, and training are needed.

At the National Association for Mental Health we have for ten years had a trained social worker providing community care for epileptics outside institutions, and nearly 1000 cases have passed through our hands. The results have been encouraging. Some indeed of the cases referred to us would have made good anyway, and for a few little or nothing can be done, but we estimate that, in more than half, the advice and encouragement that we have been able to give has been a determining factor in keeping them going. That under the Disabled Persons Act the task of finding epileptics employment is taken out of our hands in no way removes the need for community care of this type. Ideally, it should be associated with, and complementary to, the work of the D.R.O., and linked up with the patient's doctor. We should then have the framework of a real community treatment for a group of handicapped people for whom, in the past, practically no such provision has been made. Indeed a consideration of the care and provision made for certain members of society, notably the blind, the crippled, and the mentally deficient, can only lead to the conclusion that epileptics have been the victims of something like social neglect.

TWO CONCLUSIONS

There are two main conclusions to be drawn from this brief survey of some of the social aspects of the epileptic problem. One is the paramount importance of treating each patient as an individual, and avoiding any preconceived notions attaching to the group to which he belongs. In fact the basis of the social treatment of the epileptic can be expressed in the two words "avoid generalisations," a maxim that can usefully be borne in mind in the medical, as well as the social, sphere.

The other conclusion is the need for more general knowledge about epilepsy—what it is, and what it is not. Epilepsy is a tendency to recurrent attacks of loss or modification of consciousness, which may or may not be accompanied by muscular spasm, and which arises in conjunction with paroxysmal dysrhythmia of cerebral cell activity. With this one manifestation in common, a large and varied group of people is assembled. Because of ignorance and prejudice, other characteristics are commonly, but erroneously, ascribed to the group as a whole, with a resultant grievous and quite unjustifiable increase in the social handicap of many of them. Only by the removal of this ignorance and prejudice can amelioration of the lot of the epileptic be achieved. On the other side of the Atlantic, the American Epilepsy League has for years carried out nation-wide propaganda with a view to making the facts about epilepsy generally known. By books and by articles in the public and medical press, by lectures, and by broadcasting, the League is attempting to remove the deep-rooted prejudices of the past, and a perusal of their literature and reports can leave no doubt about the effectiveness of their

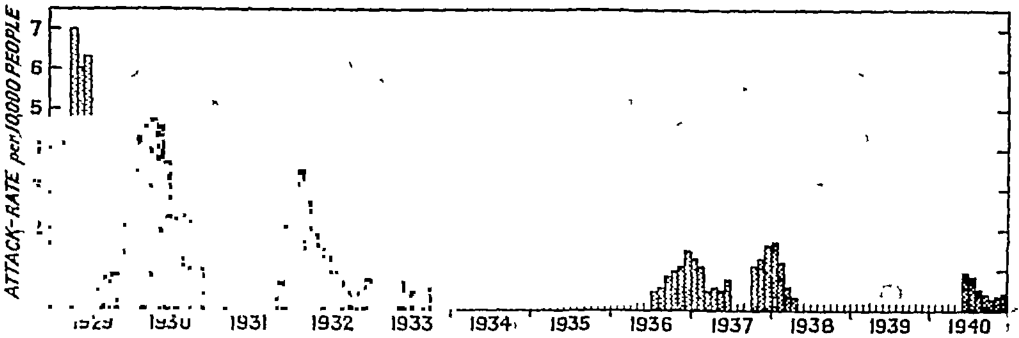

Fig. 3—Attack-rate of infective jaundice per 10,000 of urban (Reykjavik and Akureyri) and rural populations of Iceland.

polluted during the period of military occupation. Domestic washing facilities were often of the most primitive order; hence washing after defæcation would be most improbable. Disposal of fæces is often very casual, as can be imagined when no earth remains unfrozen with which to cover it. Conversely, in some rural areas a serious attempt had been made to tackle this problem.

In fig. 4 the mean urban attack-rate for 1929 and 1930 is taken as unity, and the relative attack-rate for the *affected* rural areas is superimposed. The average rate for the affected rural areas is about four times that of the urban areas, or nearly twice if one includes the unaffected rural population.

Though rapid increase in population nearly always implies domestic overcrowding, since new building cannot keep pace, it has usually meant in Iceland that the problem of water-supply and disposal of fæces has been taken in hand. In Reykjavik and Akureyri most of the houses have a piped supply which is beyond suspicion; and, though 10% still had earth closets in 1930, these were methodically emptied by the municipalities. The same applied on a smaller scale in Keflavik, Hafnafjord, and Akranes, all near Reykjavik.

Fig. 5 shows the attack-rate per 1000 of the population of each place against the percentage increase in population of that place in the ten years before 1930. Those places where there has been a diminution of population are shown simply as zero increase, because in practice the diminution of population did not mean that the remaining people spread themselves out among the surplus houses, which appeared merely to have disintegrated. It is clear that there is a highly significant inverse relation between increase in size of place and prevalence of infective jaundice.

SOURCE OF INFECTION

The explosive nature of most of the outbreaks, the predominance in rural areas where water-supply and sanitation, though varying in quality, are mostly worse than in the towns and often very primitive indeed, and the patchy distribution throughout the country, all point fæces as the prin source of reinfect a hypothesis w the dry climate, winds, and preval of dust reinforce.

The observation several other wri tend to support view. Walker (19 considered the v to be present in patients' fæces. B (1945), describing outbreak among N Zealand troops in the Alamein line, showed g evidence for spread by flies from fæces and/or fi infected corpses left half-buried by the retreat enemy.

Hallgren (1942 and 1943) described three explo outbreaks in 1942 and 1943 in Sweden which en after (1) chlorination of the relevant water-sup (2) repair of a leaky sewer which had been pollutin well, and (3) boiling of all water, which was norm taken from a river draining an area in which infective jaundice was endemic.

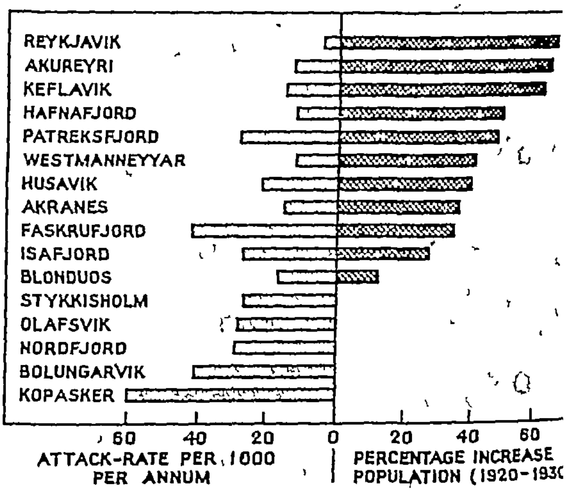

Fig. 5—Comparison of attack-rates of infective jaundice per 100 population with percentage increases of population in diffe places in Iceland.

Thorne and Estabrooke (1941) described concurrent outbreaks of bacillary dysentery and infective hepatitis in which about 22% of the patients had both diseases, and which stopped when strict measures were directed toward elimination of the intestinal-oral circuit.

Finally, Havens et al. (1945) and Findlay and Willcox (1945) showed that infective jaundice can be produced in man by ingestion of fæcal material, urine, or serum from infected patients, or by spraying the nasopharynx with fæcal material.

In Iceland one can exclude flies as vectors of any importance. Though there are parts of the island where, in summer, mosquitoes, &c., abound, infective jaundice was not in any degree localised to these areas.

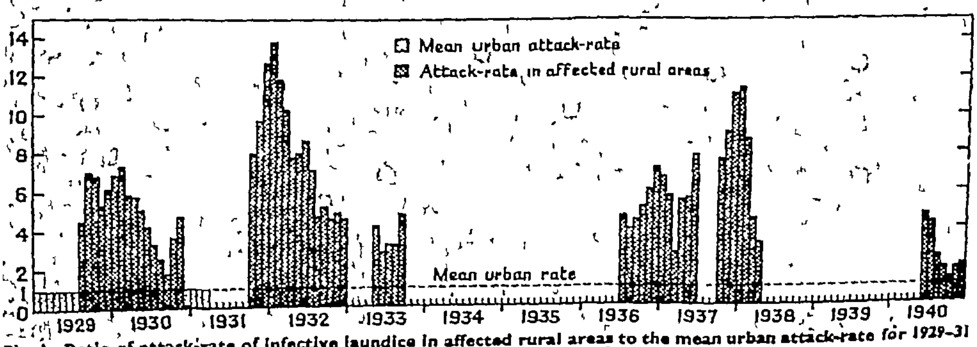

Fig. 4—Ratio of attack-rate of infective jaundice in affected rural areas to the mean urban attack-rate for 1929–31 (expressed as unity) in Iceland.

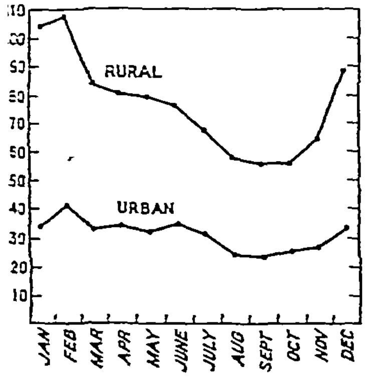
pearance of the disease in distant farms afford bstantial evidence of its incubation period.

In 1914 an instance was recorded of infective jaundice being carried by a traveller to a house in the remote district of Nanteyrar, as a result of which five people became ill; and in 1920 infective jaundice was carried from Axarfjordur (Kopasker) by the post southwards as far as Borganes, a distance of about 340 miles. In the following further examples ex-icted from these reports the possibility of infection m other sources has been excluded:



1—Seasonal incidence of infective jaundice urban and rural districts of Iceland over welve years, 1929–40.

Place	*Date*	*Sequence*	*Minimal incubation period (days)*
rdtunga ..	Early November, 1929	Woman arrives from farm where all children have recently had infective jaundice (I.J.)	
	Nov. 11	She develops I.J.	
	Dec. 12	Boy at Nordtunga develops I.J.	31
aedabolstadir	July 14, 1930	Woman arrives from infected household in Westmanneyyar	
	July 21	She develops I.J. and is isolated	
	August 21	Manservant in same house develops I.J.	31
rgsdal ..	July, 1930	Son A of farmer returns from infected house in Westmanneyyar	
	August 3	Girl A (friend) leaves Horgsdal for her home at Flotskverfi	
	August 4	Son B of farmer develops I.J.	
	Sept. 4	Girl A develops I.J. at Flotskverfi	32
	Sept. 6	Son C of farmer develops I.J.	33
	Sept. 6	Daughter of farmer develops I.J.	33
	Oct. 6	Woman at neighbouring farm to Horgsdal develops I.J.	30

These reports demonstrate the decimating effect of le disease in the little rural communities, and show the rerage minimal incubation period, in these six recorded stances, *to be 32 days, with a variation of two days.* hey agree with the conclusions of Walker (1945) conrning the U.S. Army, and of Pickles (1939), in his 'ensleydale epidemics, that multiple cases developed in milies but not simultaneously—rather were they laced, just as in Iceland, about a month apart. Hallgren .942) also noted multiple cases, developing in this stance simultaneously, in families in a Swedish rural istrict.

SEASONAL INCIDENCE

The table shows against each place its population, the umber of cases involved in the outbreak, the period overed by the outbreak, and the attack-rate. It also hows the change in population during the ten years before 1930. In the case of later outbreaks at Husavik, in 1936 the population had increased slightly since the first outbreak in 1930, and the figure of 40% increase is an average.

It was impossible to trace the start of even a majority of the nineteen outbreaks to those months when the seasonal increase in population of the places subject to variation was at its peak, and when, therefore, overcrowding and the chances of droplet infection were at a maximum.

Fig. 1 shows that in both rural and urban areas the range is about the same, the winter incidence being double that of the summer.

In many cases the epidemics tended to be of explosive onset, to reach an early peak, and to die away equally suddenly, sometimes with a second peak three or four months after the first.

AGE- AND SEX-DISTRIBUTIONS

The age- and sex-distributions, based on the 1250 cases of infective jaundice which occurred in Iceland during the twelve years, 854 of them in the nineteen epidemics and the remaining 396 sporadic cases reported from all parts of the island, are shown in fig. 2; the incidence was heaviest in children and young adults. Unfortunately the population age-group ratios for this period are not to hand; so an attack-rate cannot be calculated for age-groups. But the distribution agrees with that found by Hallgren (1943) in outbreaks among mental defectives at Strömsör Institute, and among patients, staff, and villagers at Hallnas sanatorium, Sweden: just under 46% in age-groups 5–19, 46% in groups 20–24, 24% in groups 25–34, and lower thereafter.

URBAN AND RURAL INCIDENCE

On the population trend already noted, one can assume *that the urban population will contain a far higher proportion of the childhood and young adult age-groups,* and the rural population correspondingly fewer; hence, since this is a disease of young people, the urban attack-rate might be expected to be much higher than the rural rate. That this is not the case is shown by fig. 3, which gives the urban attack-rate against that of the whole of the rest of the country. Though the two rates are of the same order of magnitude, infective jaundice tended to recur outside the two large towns.

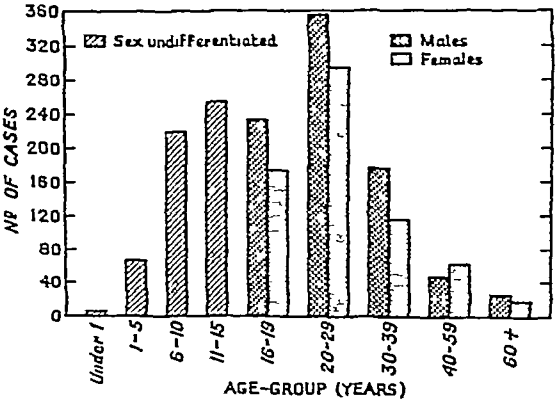


Fig. 2—Age- and sex-distributions of 1250 cases of infective jaundice in Iceland over twelve years, 1929–40.

In the country the outbreaks were confined to fourteen localities comprising 43% of the non-urban population, and infective jaundice only appeared sporadically, if at all, in the remaining areas during the twelve years.

This limitation of the outbreaks to certain areas is significant because, apart from the broad differences between farmers and fishermen already mentioned, the pattern of life throughout the country areas is fairly uniform, and therefore, if droplet infection were to blame, one would expect a measure of uniformity in distribution of the outbreaks.

Rural water-supplies and sanitation, on the other hand, are anything but *uniform.* Water was drunk from streams, wells, or lakes, and was often found to be levels after ingestion of colostrum (Howe 1921b). Similarly, *B. abortus* agglutinins appeared in calf blood only after intake of colostrum (Little and Orcutt 1922, Orcutt and Howe 1922). The dependance of the calf on natural colostrum has been confirmed and extended by Blakemore et al. (1944; see also Worden 1946). Famulener (1912) demonstrated that in the goat the greater part of artificially induced hæmolysin immunity was carried by the colostrum.

In a classical study on the transmission of immunity in the sheep, mare, cow, and bitch, Mason and colleagues (1930) emphasised that in the animal kingdom the young obtain antibodies from the mother either by diaplacental transmission or by ingestion of colostrum. In the latter case, which includes the animals studied, the permeability of the intestine would appear to be much greater than normal during the first one or two days of life.

Comparative experiments on the transmission of diphtheria antitoxin and antityphoid immune bodies through the placenta and in the colostrum have been made by Schneider and Szathmáry, who found that in sheep (1939a) and dogs (1939b) such transmission was almost entirely by the colostrum, whereas in rabbits (1939c) and guineapigs (1940), which possess a simpler placental barrier, transmission was almost entirely across the placenta. It should also be borne in mind that the permeability of the placental barrier changes during gestation—e.g., that of rabbits increases as regards agglutinins and hæmolysins from the 22nd to the 30th day (Rodolfo 1934). This phenomenon may be of considerable importance clinically and in the interpretation of the results of animal experiment.

Both active and passive sensitisation may be transferred from mother to young in utero in guineapigs (Ratner et al. 1927a and b).

Placental transmission of diphtheria antitoxin in man has been studied repeatedly, and quantitative determinations made by Kuttner and Ratner (1923) revealed that the concentration of antitoxin in the cord blood corresponded to that in the blood of the mothers.

The newborn infant is immune to measles if the mother has had measles. The passive character of this immunity was demonstrated by Herrmann (1923, 1924) and by Debré and Joannon (1926). Umbilical cord blood and the blood of the newborn infant contain antistaphylococcal antitoxin in practically the same amounts as does the maternal blood. This is lost during early infancy and is followed by a gradual rise to what is assumed to be a normal level (Bryce and Burnet 1932). A passive transfer of scarlet-fever antitoxin seems also well established, but the serum of infants usually contains little opsonin for virulent hæmolytic streptococci, and even this small amount is lost in a few weeks (Ward and Lyons 1935).

An interesting case is reported by Neff and Schwartz (1933) of an infant born three weeks prematurely of a mother in the third week of typhoid fever. The mother's Widal reaction was positive in 1 : 2560, and that of the infant's cord blood negative. The infant was bottle-fed and had no contact with the mother after delivery, but a month after birth its Widal reaction was positive in 1 : 20,480. This case suggests that the antigen rather than the antibody passed the placenta and gave rise in due course to antibody formation in the infant.

The placental transmission of syphilis and of malaria is well established, as is also that of many virus infections. Ratner et al. (1927c), reviewing the evidence, concluded that, whereas colostrum was essential for the transmission of immunity in goats and cattle, it played a negligible rôle in man. In contradiction to this view may be cited the studies of Toomey (1934) on the agglutinins against the enteric group of organisms in mother's blood, baby's blood, mother's milk, and placental blood. The agglutinins were transmitted through the placenta, but the amount was small and much less than the titre in the mother's serum. The blood-serum of the infant 10 days after birth showed a considerable increase in agglutinin titre over the placental serum; and, since the titre of the infant's serum approximately paralleled that of the mother's milk, it seems probable that the milk was the source of agglutinins. The possibility of a delayed active response, as in the case of Neff and Schwartz (1933), is difficult to exclude.

From these findings it is apparent that both active and passive sensitisation may take place in utero, but that the immunological response of the normal newborn infant is limited and but poorly developed. The part played by colostrum and milk in the defence of the human infant is still somewhat doubtful but does not appear to be large.

IMMUNITY IN THE PREMATURE INFANT

Little is known about the immune responses of premature infants, and whether they develop the ability to produce antibodies at times chronologically comparable to normal infants, though certain types of infants seem to be more susceptible to infections than the group as a whole. Thus, in an epidemiological survey (McKhann et al. 1938) of infections arising in a group of infants in hospital, only 5·5% of previously well-fed infants became infected, whereas 19% of premature infants, 35% of chronically malnourished, and 17% of luetic, eczematous, and congenitally defective infants were infected.

Will an infant, delivered at twenty-four weeks, reach immunological maturity at a date corresponding to that of its conception or of its birth? There is still a wide field for investigation of such problems. "One should not be satisfied with the term 'serologic immaturity' but must attempt to establish by chemical and physiological studies the basis of such immaturity. Is the genesis of plasma-proteins the important factor?" (McKhann and Kapnick 1938).

SERUM-PROTEIN LEVELS IN HUMAN INFANTS

Only meagre information exists about the albumin and globulin levels in the blood of newborn human infants.

Lewis and Wells (1922) reported that in 6 cord bloods examined the euglobulin fraction was below normal. Their results and those of Boyd (1922) also suggest that the ingestion of colostrum is necessary for, and is followed by, a rise in the euglobulin level.

Darrow and Cary (1933) compared the total protein concentration in sera of full-term and premature infants, finding 5·52% in the former and 4·9% in the latter. Hickmans et al. (1943) also give figures for the total protein: 4–7% in full-term infants (180 subjects), and 3·7–5·4% in prematures (20 subjects), during the first four weeks of life.

Trevorrow et al. (1942), who followed the albumin and globulin levels of normal full-term infants from the time of

43	4·23	2·87	4·44	3·23

It is difficult to entertain the view that each of the nineteen outbreaks described arose from fæcal contamination of the relevant water-supply. In a country where the disposal of excreta is so casual, where the atmosphere is dry and, because of the volcanic origin of the surface, heavily charged with fine particles of floury lava dust, and where the gales are so constant, the possibility of local spread by the inhalation or ingestion of dust contaminated by infected excreta cannot be overlooked, and indeed this hypothesis fits the facts of this survey better than any other.

This is not to exclude or to disregard the transmission of infective jaundice from person to person by contact of food and utensils with the hands, or even occasional droplet spread, but simply to suggest in the light of the Icelandic outbreaks that it can be dust-borne.

It is worth noting that there is nothing in Kirk's (1945) lucid case against droplet infection to exclude a dust-borne infection except the myriads of flies. In Iceland the circumstances, temperature apart, were much the same—namely, greater prevalence among small scattered rural groups with bad sanitation than in the relatively crowded towns where sanitation was good, together with the dust and constant high winds, but virtually no flies. Kirk's remark that there was no northward spread up the Alamein line owing to the prevailing wind being northerly is significant, as is also his observation that in a fresh unit, which occupied the ground after the New Zealanders were withdrawn, an outbreak started about one incubation period after their arrival, and that the disease left the New Zealanders shortly after they moved to fresh ground. This strongly suggests dried fæces or mummifying corpses as a reservoir.

SUMMARY

Nineteen outbreaks of infective jaundice in Iceland between 1929 and 1940 are analysed.

The social and economic structure of Iceland is briefly described.

The whole population is shown to have increased by 57% in the forty years before 1930, and the proportion of urban population from 15% in 1910 to 29% in 1930.

The seasonal distribution of infective jaundice is the same in rural and in urban areas.

The incidence of infective jaundice is greatest in school-children and young adults, which age-groups are probably heavily weighted in urban areas.

In spite of this the rural attack-rate in the affected areas is four times higher than the rate in the towns, where disposal of excreta is more efficient.

The incidence of infective jaundice is in inverse relation to recent increase of population in any given place.

Conditions for droplet spread are most favourable in the towns, where, however, the attack-rate is lowest.

Evidence is offered which suggests that in many cases infection may be due to dust-borne dried excreta.

I wish to thank Prof. F. A. E. Crew; Dr. Vilmundur Jonsson, chief medical officer for Iceland, without whose ready coöperation these observations could never have been made; and Lieut.-Colonel S. C. Truelove, D.M.(S.)R. War Office, for kindly advice and criticism.

PRE- AND POST-NATAL DEVELOPMENT OF IMMUNITY

SERUM-ALBUMIN AND SERUM-GLOBULIN LEVELS IN MATERNAL AND CORD BLOODS OF PREMATURE INFANTS

C. RIMINGTON
M.A., Ph.D. Camb., B.Sc. Lond.
PROFESSOR OF CHEMICAL PATHOLOGY IN THE UNIVERSITY OF LONDON, AT UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

J. A. BICKFORD
M.B., B.Sc. Lond., M.R.C.P.

With the technical assistance of J. EVANS

VERY little is known about the serum-protein levels of infants and their mothers at and before parturition, and our knowledge of the early biogenesis of serum-albumin and serum-globulin is therefore largely conjectural. The present investigation was undertaken to fill this gap and so provide a basis for a possible relation between susceptibility to neonatal infections and the degree of development of the protein-elaborating mechanisms.

NEONATAL INFECTION

Prematurity, asphyxia, birth injury, and congenital deformity cause more than two-thirds of the deaths in the first few weeks of life, most deaths taking place within a week of birth (Cruickshank 1946). Infection, which is relatively unimportant as a cause of death during the first week, becomes the major cause in succeeding weeks, when bronchopneumonia and gastro-enteritis are the principal causes of mortality.

Corner (1946) reported that in one hospital 25·3% of all newborn infants acquired some infection, 3 dying of bronchopneumonia, and in a second hospital 29·9% acquired infection, 5 dying of gastro-enteritis, the death-rates from infection in the two hospitals being 0·89 and 3·76 per 1000 live births during the period under review.

Many factors contribute to the high incidence of neonatal infection—e.g., adverse environment (Cruickshank 1946) and inadequate nutrition (Clausen 1934)—but the most important must be the poorly developed immunological response of the newborn, called by Hirszfeld (cited by McKhann and Kapnick 1938) "serologic immaturity."

Clinical observations have established that the newborn are immune to some diseases but susceptible to others; thus, there is a substantial immunity, lasting several months, to measles, scarlet fever, poliomyelitis, and diphtheria, but the newborn are susceptible to pyogenic and colon-bacillus infections and to pertussis, and staphylococcal infections are particularly virulent in early infancy. Pneumococcal infection is uncommon in the early weeks of life but thereafter rises in incidence and tends to be of a diffuse infiltrating type; meningeal involvement is common (Fothergill and Sweet 1933).

IMMUNITY IN THE NEWBORN

An analysis of the resistance displayed by the newborn shows that two factors require consideration: (1) passive transient immunity derived from the transmission of maternal antibodies or antigens across the placenta or through the mother's milk; and (2) the active immunological responses of the infant itself.

Some years ago a considerable amount of work was done on the placental transmission of antigens and antibodies both in animals and man, and interest in this subject has recently revived.

Smith and Little (1922a) found that 75–80% of calves not fed colostrum died from colon-bacillus septicæmia, but that cow's serum administered by mouth or by injection was protective (Smith and Little 1922b). The proteinuria exhibited by the normal calf coincides with the period of intake of colostrum (Lewis and Wells 1922). Howe (1921a) showed that the blood of the newborn calf was deficient in euglobulin and pseudoglobulin, but that both rose rapidly to normal and globulin levels in cord blood and the age of the fœtus. The regression lines were calculated from the respective statistical equations. A regression equation expresses the rate of change of a variable with respect to unit change in another quantity, and graphically the regression line is the mathematical "line of best fit." A multiple regression equation, as used in the appended statistical analysis, similarly relates the rates of change of two variables each changing with respect to a third quantity. Only by adopting such mathematical procedures can precise relationships be established with certainty from observations showing an appreciable degree of scatter as in the present instance.

Though the scatter of individual determinations is fairly considerable, the statistical evidence shows clearly that fœtal albumin and globulin increase at approximately the same rate, as may be seen from the equal slopes of the regression lines in figs. 1 and 2.

Calculation of the conventional A/G ratio has been purposely omitted from the table because, in this case particularly, it would obscure rather than illuminate the position. Thus the A/G ratios for the twentieth and fortieth weeks are 4·47 and 1·76, figures which do not bring out the equally rapid increment of the two proteins during this time. The mean fœtal albumin and globulin at full term were found from this investigation to be 4·16 and 2·37 g. per 100 ml. of serum.

DISCUSSION

The finding that the rates of increase of albumin and globulin from the twentieth to the fortieth week are similar is somewhat surprising. The absolute amount of albumin is, however, greater than that of globulin, and it is clear that an infant born prematurely—e.g., at thirty weeks of fœtal age—will *start* life with a considerably lower globulin level than will a full-term baby. The evidence relating to the transplacental passage of proteins from the mother to the fœtus has been discussed above; but if, as seems likely, the greater part of the serum-proteins, both albumin and globulin, are being synthesised by the fœtus, the parallelism in the rate of their formation tempts one to speculate whether, at this stage, one and the same mechanism is elaborating both albumin and globulin. The general view regarding the origin of the immune bodies of globulin nature is that these are elaborated in the adult either by the cells of the reticulo-endothelial system or possibly by lymphocytes (see Landsteiner 1945), but the newborn is deficient, as has been pointed out, in antibody globulins, and only slowly acquires the ability after birth to produce them.

A globulin component, fetuin, characteristic of the fœtal stage and disappearing as the fœtus matures, has been demonstrated in the calf and sheep (Pedersen 1945). In these animals it makes up 48–68% of the total globulin. A protein differing physicochemically in similar degree from the globulins of the adult is also present in human fœtal serum and that of the fœtal rabbit, but the quantity is much less, about 2–6% of the total globulin. In serum from chicken embryos it could not be detected ultracentrifugally, but its presence was suggested by the asymmetry of the albumin peak (see Pedersen 1945). The study of Trevorrow et al. (1942) shows that there is a *fall* in the serum-globulin of the infant from the first to the fifth week of life, and the existence of a fœtal type of human hæmoglobin which gives place, shortly after birth, to adult hæmoglobin is well established. The hypothesis may well be entertained that globulin and possibly albumin are synthesised by a special mechanism in the fœtus which becomes progressively less important as the adult mechanism develops. The serological immaturity of the newborn, especially of the premature infant, would then be understandable, and from the point of view of practical immunology a closer study of the reticulo-endothelial and lymphatic systems of the newborn would be indicated.

The data presented here also suggest that the osmotic relations of the premature infant, with a relatively low total serum-protein, would be of peculiar interest. At twenty weeks the mean total protein is only 3·1%, and values of less than 3·5% were encountered in some of the older infants. In this connexion reference may be made to the studies of McCarthy (1938, 1942) on the osmotic pressures of fœtal sheep and horse serum-proteins. The unusually high osmotic pressure per g. of protein, which he observed in the sheep, may have been due to fetuin.

SUMMARY

Very little information exists about the serum-protein levels of full-term and premature infants.

Determinations have been made of the total protein, non-protein nitrogen, albumin, and globulin in the maternal and cord blood from 38 cases, mainly of premature birth, the youngest fœtuses being twenty weeks old.

The fœtal albumin and globulin increase with the length of gestation and at about the same rate. Mean full-term values were 4·16 g. per 100 ml. for albumin and 2·37 g. per 100 ml. for globulin.

The maternal albumin and globulin are not affected by the length of gestation in the period studied and are only slightly correlated with the fœtal values.

The bearing of these results on immunity and the biosynthesis of the serum-proteins is discussed, and it is suggested that there may be a fœtal mechanism of synthesis of both albumin and globulin which becomes relatively less important as the adult mechanisms of synthesis develop and take its place. The serological immaturity of the newborn would be understandable on this basis, and evidence is brought forward in support of this suggestion.

Statistical treatment of the results shows that the regression coefficients of both albumin and globulin on length of gestation are highly significant.

APPENDIX

Statistical Analysis of Relationship between Fœtal and Maternal Proteins and Duration of Gestation.—As a first step, two multiple regressions were calculated: (1) that of duration on maternal and fœtal globulin; and (2) that of duration on maternal and fœtal albumin. It was thought that this would improve the fit of the relation between fœtal protein and duration by eliminating the maternal variability. It also allowed a test to be made of the significance of the regression of maternal protein on duration. The analyses of variance resulting from this investigation are as follows:

FŒTAL AND MATERNAL GLOBULIN: REGRESSION ON DURATION

	Sum of Squares	*Degrees of Freedom*	*Mean Squares*
Regression on fœtal protein	407·2689	1	407·2689
Improvement from introducing maternal protein .	3·5808	1	3·5808
Error	716·2033	35	20·4630
Total ..	1127·0530	37	

FŒTAL AND MATERNAL ALBUMIN: REGRESSION ON DURATION

	Sum of Squares	*Degrees of Freedom*	*Mean Squares*
Regression on fœtal protein	758·8112	1	758·8112
Improvement from introducing maternal protein ..	8·9710	1	8·9710
Error	359·2708	35	10·2649
Total ..	1137·0530	37	

In both cases the regression of fœtal protein on length of gestation is significant, whereas the improvement in the fit

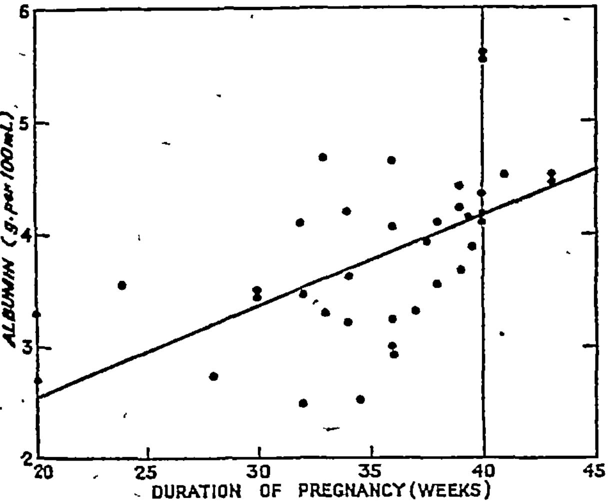

Fig. 1—Relation between amount of albumin in cord blood and duration of pregnancy. Regression equation, where A=albumin in g./100 ml., and T=length of gestation in weeks: $A = 0{\cdot}9536 + 0{\cdot}08007\,T$.

birth until adult values were reached, reported a mean albumin level at birth of 3·79±0·33%, beginning to rise after about a month, until the adult level of 4·70±0·32% was reached at six months to a year of age. A seasonal variation was also apparent. Globulin at birth was 1·66±0·29% and fell from the first to the fifth week to a value of only 1·31±0·25%. After this it remained steady for about six months and then rose gradually (four years) to an adult level of 2·03±0·34%.

Rapoport et al. (1943), from a study of 17 premature infants (birth-weight under 5 lb.) and 17 full-term babies, confirm the low total serum-protein of premature infants—4·55±0·59% against 5·11±0·76% at full term—and in particular the low globulin value—1·01±0·45% against 1·34±0·41% at full term. They point out that the globulin is still low in the infant at a time when the albumin reaches the adult level. It is the euglobulin or γ-globulin fraction (by salt precipitation) which they consider to be deficient in infancy.

A discrepancy between the human serum-protein levels in maternal and cord blood at full-term delivery was reported by Rinehart (1945), who claims to have been the first to provide such information. He found little difference in albumin level but consistently less globulin in the cord blood. Similar results were reported by Achard et al. (1930).

Longsworth et al. (1945) have applied the Tiselius electrophoresis method of separation of the individual globulin fractions to this problem, and in 10 pairs of maternal and fœtal plasmas or sera have shown that the distribution of globulins is different in the two. Judged by this method, the maternal concentrations of α_1, α_2 globulins and especially the β-globulins are above normal, whereas in the cord blood β-globulin tends to be below normal and the γ-globulin both relatively and absolutely above normal.

The discrepancy between these conclusions and those of Rapoport et al. (1943) and of Lewis and Wells (1922) is probably due to the difference in methods used. The question is important, since it is the γ-globulin fraction which carries most of the immune bodies. Nevertheless, taken together, the globulins of the fœtus were always distinctly lower than those of the mothers, affording a high albumin/globulin (A/G) ratio. No premature infants were studied.

METHODS USED IN PRESENT INVESTIGATION

Material.—The material comprised maternal and cord blood from 30 cases of premature birth and 8 cases of normal or over full-term pregnancy; cases of pregnancy toxæmia, &c., were excluded. The earliest fœtuses obtained were twenty weeks old, pregnancy in these cases having been terminated by surgical intervention.

Duration of Pregnancy.—The age of the child was computed from clinical records and information supplied by the mother.

Blood Specimens.—Blood samples were taken from the mothers by venepuncture, usually at the onset of labour, with dry syringes, and after delivery, from the placental end of the cord by pouring. The blood was allowed to clot, and the serum was separated, centrifuged, and analysed with as little delay as possible. Many of the cord bloods clotted very slowly, but no correlation with age of fœtus was apparent. All possible precautions were taken to avoid hæmolysis, and any badly hæmolysed samples were rejected.

Analysis.—All determinations of proteins were made by the micro-Kjeldahl method. The technique adopted also allowed of the determination of non-protein nitrogen (N.P.N.) as follows:

(1) *Total protein + N.P.N.*: 0·1 ml. of serum used for digestion, &c.

(2) *Total protein*: 0·1 ml. of serum was mixed in a centrifuge tube with 2·4 ml. of water and 2·5 ml. of 10% (w/v) trichloroacetic acid. After standing for about 10 min., the precipitate was centrifuged and drained by inverting the tube over filter paper. 0·5 ml. of 2N sodium hydroxide was then added to dissolve the precipitated protein, and the solution was transferred quantitatively to the micro-incineration flask with a capillary pipette, the centrifuge tube being rinsed first with 0·5 ml. of water and then with 2 lots of 1 ml. each of digestion acid.

(3) *Non-protein nitrogen*=(1)−(2).

(4) *Albumin*: 0·1 ml. of serum was mixed with 1·9 ml. of 42% (w/v) crystalline sodium sulphite, and after half an hour at room temperature the mixture was filtered through a no. 42 Whatman paper and 1 ml. of the clear filtrate used for nitrogen determination. The albumin value so obtained was corrected for the N.P.N.

(5) *Globulin*=(2)−(4).

On several occasions the results found by this method were checked by ammonium or sodium sulphate precipitation and found to be reliable. The micro-Kjeldahl procedure was in each case as follows:

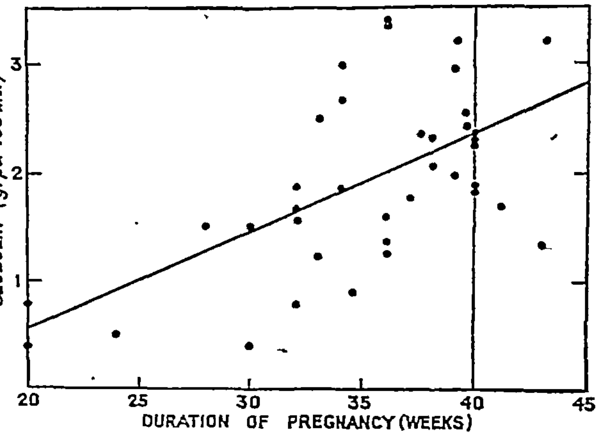

Fig. 2—Relation between amount of globulin in cord blood and duration of pregnancy. Regression equation, where G=globulin in g./100 ml., and T=length of gestation in weeks: $G = -1{\cdot}1837 + 0{\cdot}08878\,T$.

For incineration 2 ml. of a solution of 50% (w/v) sulphuric acid containing 1% selenium dioxide was used for each sample. A drop of saturated copper sulphate solution was also added, and heating was carried on for two hours after the mixture became clear. In distilling, 4 ml. of 50% (w/v) sodium hydroxide was used for alkalinisation, and the distillate (5 minutes) was collected in 10 ml. of saturated boric acid (A.R.) solution. The ammonia was titrated directly to match the blank by $N/70$ sulphuric acid, 3 drops of methyl red being used as indicator. The factor 6·25 was used to convert nitrogen to protein values.

Statistical Analysis.—The results have been subjected to a rigid statistical analysis, and regressions have been calculated (see appendix).

RESULTS

The data obtained are presented in the table and in figs. 1 and 2, which show the relation between albumin

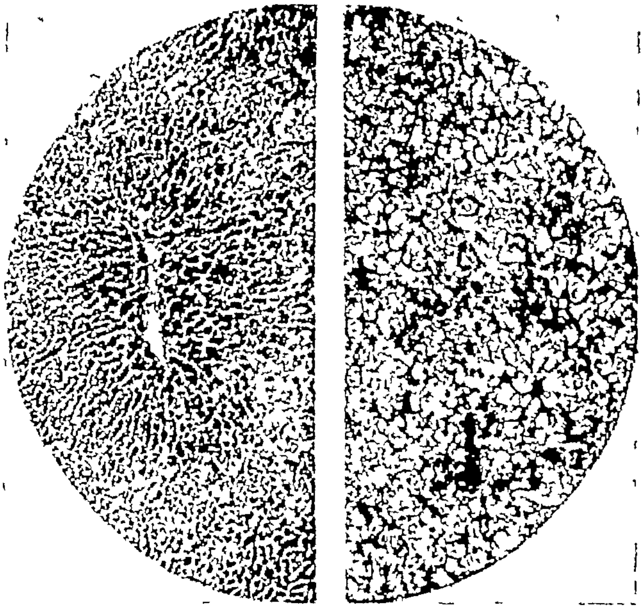

Fig. 1—Left: section of liver nodule stained by Best's method for glycogen and showing depreciation of glycogen. **Right:** section of adenoma of pancreas showing closely packed rosette formations of cells. (× 44.)

so closely resembled that of hysteria that, as physical signs were absent, he would probably have been sent home if his doctor had not reported a history of suspected hypoglycæmia.

Next day he seemed normal and gave the following history. For three and a half years he had at times had attacks of giddiness, headache, and tingling, which spread from the feet to the waist and were occasionally noticed in the lips and mouth. These attacks always occurred on rising in the morning; but, curiously, the effect of taking food had not been remarked. Soon after the onset he began to have attacks of unconsciousness starting usually about noon and lasting about an hour; on recovering consciousness, according to his relations, he behaved like a drunken man, talking incoherently and staggering about. He would go to bed and be normal by next morning. There had been periods of freedom from attacks for as long as twelve months, but latterly the early morning symptoms had occurred about three times a week. Apart from these attacks his health was good.

Clinical examination was entirely negative. His physique, though spare, was good, and though understandably interested in his health he did not appear in any way neurotic.

A few days after admission, when about to start his dinner, he became suddenly drowsy and lapsed into deep coma, accompanied by profuse sweating but with no other abnormal findings apart from extensor plantar responses. He was given 50 c.cm. of 50% glucose intravenously and rapidly recovered consciousness. On another morning drowsiness and sweating at midday were relieved by 5 minims of adrenaline hydrochloride.

(1) *Glucose-tolerance Test* (50 g. of glucose by mouth).

Hr. after glucose		*Blood sugar (mg./100 c cm.)*	*Hr. after glucose*		*Blood-sugar (mg./100 c.cm.)*

1/2	..	125	2 1/2	..	40
1	..	128	3	..	40
1 1/2	..	80	3 1/2	..	40

(2) *Prolonged Fasting*

Hr. after meal		*Blood-sugar (mg./100 c.cm.)*	*Hr. after meal*		*Blood-sugar (mg./100 c.cm.)*
12	..	45	16	..	45
13	..	45	17	..	35
14	..	45	18	..	35
15	..	35			

At eighteen hours symptoms of hypoglycæmia developed and food was given.

Operation (Mr. B. T. Rose).—The tail and body of the pancreas were normal. Embedded in the anterior surface of the upper part of the head of the pancreas was a discrete encapsulated tumour of firmer consistence than the rest of the gland, and about the size of a small cherry-stone. This was removed without difficulty; and, when its character had been established by a frozen section, abdomen was closed. The liver appeared normal.

Postoperative Course.—Recovery was uneventful, apart f a transient external-rectus palsy attributed to spinal thesia.

A glucose-tolerance test (50 g. of glucose by mouth) done three weeks after the operation gave the following figures:

Hr. after glucose		*Blood-sugar (mg./100 c.cm.)*	*Hr. after glucose*		*Blood-sugar (mg./100 c.cm.)*
Fasting	..	110	1 1/2	..	130
1/2	..	160	2	..	155
1	..	170			

Four months after the operation no further symptoms of hypoglycæmia had occurred and the man was well.

Pathological Report.—Two specimens were sent for histological examination: the pancreatic tumour and a nodule from the liver.

The pancreatic tumour was 0 5 cm. in diameter. A thin capsule surrounded the tumour mass, clearly demarcating it from the adjacent pancreatic acinar tissue. The tumour consisted of closely packed small rosette formations of cells (fig. 1). The cells were fairly uniform in shape and size. One of the first impressions obtained was the well-marked vascularity, and on closer examination under high power many of the acinar structures were seen to possess a lumen containing blood (fig. 2). Also, several large blood-vessels traversed the adenoma. The rosette formations were each surrounded by a fine layer of connective tissue, and a few coarser intersections of fibrous tissue were seen running across the adenoma. Neither hyaline degeneration nor calcification, which are features often observed in the islet cell adenoma, was present.

A uniform cellular tumour of the pancreas with a definite capsule and associated clinical manifestations of hypoglycæmia point to the diagnosis of an islet-cell adenoma. A portion of the tumour was stained for specific granules by the method of Dunn et al. (1944). This procedure gave a uniform blue colour to all of the adenoma cells, which contrasted with the bright red erythrocytes in the blood-vessels and small sinuses, thus indicating a tumour composed of the beta cells of the islets of Langerhans.

The liver nodule was fixed in alcohol, and sections were prepared and stained by Best's method for glycogen. They showed some depreciation of glycogen at the periphery of the liver lobules (fig. 1).

SUMMARY

A classical case of adenoma of the islets of Langerhans is reported which presented no difficulty in diagnosis at the stage at which it was seen.

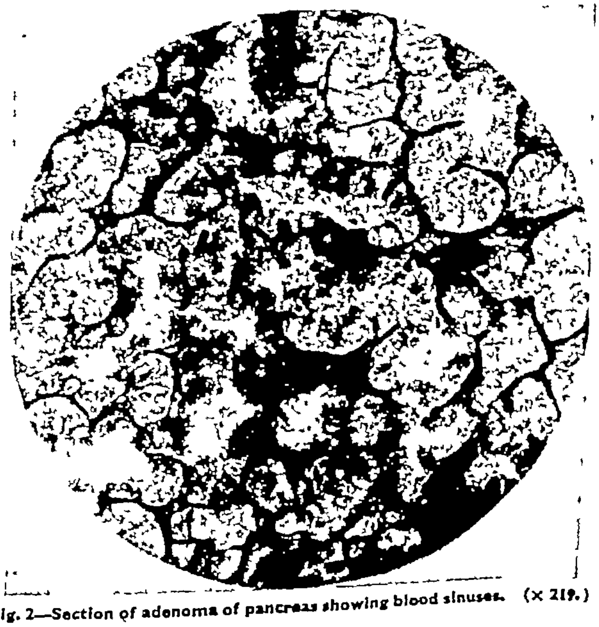

Fig. 2—Section of adenoma of pancreas showing blood sinuses. (× 219.)

resulting from the introduction of maternal values is negligible. The regression coefficients of maternal proteins are not significant in either case. The fœtal regression equations uncorrected for maternal protein are:

$$D = 27{\cdot}2709 + 4{\cdot}0705\ G$$
$$D = 20{\cdot}5301 + 3{\cdot}8814\ A$$

A further regression was calculated of the fœtal albumin and globulin on duration. This allows a test to be made of the significance of the difference between the rates of increase of the two proteins. The equation is:

$$D = 18{\cdot}8794 + 3{\cdot}1097\ G + 2{\cdot}7206\ A$$

The regression coefficients are both highly significant, but the difference between them, 0·3891, has a standard error of 1·4633 and is clearly not significant.

We are greatly indebted to the colleagues who have assisted us in the supply of material and to the assistant and nursing staffs of the hospitals concerned. In particular we wish to thank Sir Allen Daley, Prof. W. C. W. Nixon, Prof. Aleck Bourne, Prof. J. Young, Prof. F. J. Browne, Dr. K. M. Harding, Dr. M. F. Butler, Dr. A. Carter, Dr. H. Walker, Dr. E. Field, and Dr. M. Thornton. We are especially grateful to Prof. J. C. Spence, Prof. A. St. G. Huggett, and Prof. A. N. Worden for their interest in this investigation, and to Dr. S. Way for procuring the very early fœtuses for us and for much helpful discussion. We have also received information relative to methods from Dr. D. P. Cuthbertson and Dr. W. Young. Finally, we wish to acknowledge the assistance of Dr. C. C. Spicer, of the British Bombing Survey Unit, who kindly subjected our results to statistical analysis.

HYPOGLYCÆMIA DUE TO ISLET-CELL ADENOMA OF PANCREAS

CURED BY OPERATION

R. L. BISHTON
M.B. Birm.
ASSISTANT PATHOLOGIST

J. M. MALINS
M.B. Birm., M.R.C.P.
ASSISTANT PHYSICIAN

BIRMINGHAM UNITED HOSPITAL

AFTER the discovery of insulin, Harris (1924) suggested the possibility of hyperinsulinism occurring as a disease in contrast to the hypo-insulinism of diabetes mellitus. Gray and Feemster (1926) published a case of hypoglycæmia associated with islet-cell hyperplasia in the infant of a mother who had severe diabetes. The first recognised case of hyperinsulinism due to a pancreatic tumour was reported by Wilder et al. (1927), the lesion being a carcinoma of islet tissue. The growth had produced metastases, one of which yielded an extract which gave the biological reactions of insulin.

Surgical treatment of the condition was then considered, and Roscoe Graham (Howland et al. 1929) excised a pancreatic tumour with clinical cure. No metastases were seen at the operation, but the tumour, which appeared to be encapsulated, was reported histologically as a slowly growing carcinoma of islet tissue. Next year (1930) Harvey Cushing reported the removal of a benign adenoma of islet cells with resultant abolition of hypoglycæmic attacks. Several papers have since been published on the subject from both the clinical and the histological aspects.

Laidlaw (1938) suggested the term nesidioblastoma for the simple islet-cell adenoma. He discussed the origin of the tumour on an embryological basis, and, using the Greek word for islet, coined the word nesidioblast for the cell which differentiates out of the duct epithelium to form the islet. Hence the benign tumour arising from these cells would be a nesidioblastoma.

Surgical Pathology

The following points are important to the surgeon. Hyperinsulinism is probably due to a tumour of the pancreatic islets and may be either benign or malignant. Laparotomy settles the diagnosis. It is worth noting that Anderson (1930) reported a case of hypoglycæmia which proved at operation to be caused by a malignant adrenal tumour; no explanation of the mechanism was offered.

The simple adenoma is usually small, the average diameter being about 1·5 cm. It is encapsulated and is commonly encountered in the tail of the pancreas, where the islets are most numerous. Multiple tumours may be present; hence the whole of the pancreas should be palpated, particularly the tail. Occasionally no pancreatic tumour is detected at laparotomy. This may be due to one of two reasons: (1) an adenoma is present but lies deep in the pancreas and is of the same consistence as the surrounding tissue; or (2) the lesion is a generalised overactivity on the part of the islets of Langerhans due to increased number or size. Subtotal pancreatectomy has been performed in the cases presumed to be of the latter type, but the results have not been so successful as those in which a tumour has been excised (McCaughan 1935).

The question of malignancy concerns the surgeon, and apparently the presence of a capsule does not altogether exclude malignancy (Howland et al. 1929). Metastases should therefore be looked for at the operation, although of 62 cases of islet-cell tumour reviewed by Whipple and Frantz (1935) only 3 were reported to have shown metastases.

CASE-RECORD

A dancing teacher, aged 49, was admitted to the General Hospital on June 5, 1945, in a stuporose state. His condition breast and begin to feed at once, the last explanation would be the one of choice so far as they were concerned.

SUMMARY

The blood-urea level is higher on the third day of life than it is at birth or on the sixth and subsequent days.

The functional dependence of the kidney on the state of hydration of the body is the most important reason for the rise and for the subsequent fall.

We are much indebted to Prof. K. J. Anselmino for welcoming us at the Landesfrauenklinik, and to Dr. M. A. von Finck and other members of the staff there for their coöperation. Some of the technical work was done by Frl. I. Arrenberg.

POSTVACCINAL ENCEPHALITIS

TWO PROBABLE CASES IN AFRICAN CHILDREN

J. N. P. Davies
M.B. Brist.
MEDICAL OFFICER, COLONIAL MEDICAL SERVICE, UGANDA

Postvaccinal encephalitis, though not uncommon in Europe, appears to be very rare in the tropics, where virulent smallpox is so much more common and vast vaccination campaigns are continually in progress. Cases have been reported from British Guiana (Grace 1930), Mexico, India, and Oceania (van Rooyen and Rhodes 1940), but only one case seems ever to have been recorded in an African (Stott 1945). In view of the millions of vaccinations performed yearly in Africans this immunity is striking and may be connected with the African immunity to other demyelinising diseases of the central nervous system. The two probable examples here reported thus have more than local interest.

Both children resided at the Kumi Leper Settlement, under the care of Miss M. Laing. In May, 1945, a case of smallpox having occurred in the vicinity, it was decided to vaccinate all the 400 children in the settlement, as this had not been done for some years. The multiple-scratch method was adopted, the bigger children having three scratches and the smaller two. The lymph was manufactured in East Africa from seed lymph of a strain obtained from Tanganyika which had been rabbit-passed; there had been no recent change in the method of production. Apart from 3 children with swollen arms, only 2 of the 400 children showed any ill effects, and in these 2 the acute stages of the illness were very similar.

Both were primary vaccinations, and on the fourteenth day after vaccination each child was taken ill with drowsiness, headache, vomiting, meningismus, pyrexia ranging up to 99–100°F, pulse-rate 90–100 per min., respirations slightly increased. Both had stiffness in the joints and appeared to have diplopia, but neither was incontinent. Quinine was given for seven days without effect, the temperature mounting towards the end of the course till on the seventh day it was 101–102°F, pulse-rate 100 per min. It was then suspected that they had meningitis, and from the eighth to the fourteenth day sulphapyridine was administered by mouth. By the tenth day the temperature had begun to fall and there was much clinical improvement, yet the pulse-rate was still 100 per min. Unfortunately they were not seen by a doctor during the acute stages, and no lumbar punctures were performed.

CASE-RECORDS

Case 1.—A male Mugishu child, aged 2 years, became paralysed in both legs about the fifth day of illness (19th day after vaccination) and could not walk; legs apparently not painful, but sensation seemed to be affected. Full power came back within a few days to the right leg, and he could stand on it.

When seen in August, 1945 (four months later), he stood with the left leg extended, rotated and abducted at the hip, partially flexed at the knee, plantar flexed at the ankle, and abducted at the mid-tarsal joint. There was weakness of the flexors, extensors, and abductors of the thigh, with complete paralysis of the calf muscles and the extensors of the leg and foot. The peronei and the short flexors were not much affected. The tone was flaccid; tendon reflexes absent; plantar response extensor; sensation apparently normal; wasting extremely slight.

Right leg: ankle and knee jerks absent; plantar response extensor; sensation apparently normal. No other lesions elsewhere in the body.

In September lumbar puncture was performed. Cerebrospinal fluid (C.S.F.) contained 2·5 cells per c.mm., protein 25 mg. per 100 c.cm. Kahn reaction negative in C.S.F. and blood.

Revaccination on Oct. 5 produced no reaction.

Case 2.—A female Mugishu child, aged 4 years, lost the use of both legs about the fourth day of illness (18th day after vaccination) but recovered rapidly, and it was only after the illness was over that it was noted that the left arm was paralysed.

Examination in August revealed a scar of successful vaccination over the left deltoid muscle. Apart from chronic right otorrhœa, the clinical findings were confined to the left arm. There was flaccid weakness of the arm and forearm, with very slight muscular wasting of the muscles of the whole limb, but no apparent sensory change. All tendon reflexes were abolished. Patient could dorsiflex wrist and extend and flex third and fourth fingers, and extend middle and index fingers slightly. Kahn test of blood gave a negative result.

DISCUSSION

As neither case ended fatally, no certain diagnosis can be given; but the occurrence, in a closed community of over 400 children, of 2 cases showing evidence of encephalitis starting within fourteen days after vaccination and leaving residual monoplegias strongly suggests postvaccinal encephalitis. Syphilis has been serologically excluded; and, though poliomyelitis has occurred in the vicinity but not in the settlement, there are several reasons why it was not considered to be the causal condition in these two children. The extreme flaccidity of the limb paralysis, associated with loss of tendon jerks and with extensor plantar responses and extremely slight wasting of the muscles, is against a diagnosis of poliomyelitis (Brain 1940). Likewise the selection of single limbs, rather than asymmetric patchy lesions, is against a diagnosis of poliomyelitis. The clinical picture as a whole did not resemble poliomyelitis, which is all too well known in Uganda.

The illness was not very like meningitis; and, though monoplegias may follow meningitis, it is extremely unlikely that two sporadic cases in a closed community would occur and leave such a rare sequel. Though meningitis is common in the vicinity of the colony, residual monoplegias have not been seen. Neal (1942) states that she believes that a diagnosis of postvaccinal encephalitis cannot be made by clinical observation, but such a diagnosis in these cases seems reasonable.

If this is the true diagnosis, the question arises why it is so rare in Africans in Africa and why two cases should crop up. It seems very unlikely that such a dramatic sequel to vaccination should occur without being noticed in such a well-vaccinated country as Uganda, where the population in many areas is very "hospital

The response to adrenaline during a hypoglycæmic ttack suggested that the liver glycogen was not comletely deficient, and this was confirmed by the histoogical examination of a biopsy specimen of liver.

Surgical removal of the adenoma completely cured he hypoglycæmia.

We wish to thank Dr. A. B. Taylor and Mr. B. T. Rose for ermission to publish this case.

BLOOD-UREA IN THE FIRST NINE DAYS OF LIFE

R. A. McCANCE
M.D., Ph.D. Camb., F.R.C.P.

E. M. WIDDOWSON
B.Sc., Ph.D. Lond.

From the Medical Research Council, Department of Experimental Medicine, Cambridge; and Wuppertal, B.A.O.R.

WHEN the introduction of micro methods first made determinations of the so-called serum chemistry a practical possibility, it was natural that investigators, interested in the metabolism of infants, should apply these methods to children in the first few days of life.

Schlutz and Pettibone (1915) were probably the first in the field and they were followed by Sedgwick and Ziegler (1920), Balint and Stransky (1920), Lucas et al. (1921), and Sherman et al. (1925). A study of their results for non-protein nitrogen (N.P.N.) and urea shows great individual variations and the unsatisfactory nature of their averages for determining the trends from day to day. Lucas et al. (1921) included studies of the blood at birth, but no serial determinations seem to have been made by any of these workers, and curiously little work appears to have been done on this subject since that time. The obvious shortcomings of these studies were not lost upon Smith (1945), who was unable to draw any firm conclusions from the evidence about the day-to-day levels of the N.P.N. or of the blood-urea.

The present investigation was undertaken as part of a more general study of renal function in early life.

SUBJECTS AND METHODS

The subjects were all normal full-term babies. They were put to the breast for the first time when they were 18–24 hours old, and they were given nothing but mother's milk. Their progress was regarded as completely satisfactory. Samples of blood were taken from the umbilical cords at birth, and from the heels on the third, sixth, and eighth or ninth days of life. The second and subsequent samples were usually taken at 10 A.M., but this was not invariable. Coagulation was prevented with sodium oxalate, and the urea was determined by Lee and Widdowson's (1937) method.

RESULTS

The results are given in the accompanying table, which shows that in every case there was a rise in the blood-urea level on the third day of life, and a fall later. In some babies the blood-urea level probably reached its peak on the second or fourth day, but there is insufficient data to establish this point. It is, however, quite clear that a small rise in blood-urea level is to be expected in the first few days of life, and that levels outside the "normal" range should be regarded as unusual and possibly as pathological.

DISCUSSION

A steady blood-urea level indicates that a balance exists between the forces of production and of excretion. A rise, therefore, in the first three days of life means that during this time the production of urea is exceeding its excretion, for the 5–10% concentration of the body fluids which may take place at the same time would only account for a fraction of the changes observed.

In the first three days of life a baby takes little food; hence the urea produced from the proteins in the milk will be immaterial. But red blood-cells are being destroyed, and some urea is being formed from the breakdown of the proteins of some tissues to supply the needs of other more essential organs. A relatively large amount of urea may be coming from this source, for in the first few days of life babies are in a state of hydropenia, and this has been said to exaggerate tissue breakdown. The evidence for this has been discussed by Schiff (1929) and McCance (1936). It seems improbable, nevertheless, that more urea will be formed from the tissue proteins in the first three days of life than from the food proteins in the second three days; hence it is unlikely that an overwhelming production of urea is the cause of the rise in concentration of this substance in the blood.

There is abundant evidence, however, that hydropenia will curtail very materially the ability of a newborn child to excrete urea (McCance and Young 1941, Young and McCance 1942). By reducing the volume of the urine, moreover, and hence the urea clearances, hydropenia may produce a comparable rise of blood-urea level in an adult (Black et al. 1944). The rise in the blood-urea should therefore be attributed primarily to the effects of hydropenia on renal function, and the fall after the third day—in spite of the increased intake of protein food—primarily to the infant's return to a state of full hydration and consequently to increased urea clearances.

One further reason may be advanced for the rise and fall in the blood-urea level revealed by these investigations. The kidney is relatively inefficient for some time after birth, and it is possible that a rapid expansion in its functional capacity takes place in the first few days of extra-uterine existence. There is no evidence on this point at present in man, but if a rise in blood-urea level is found to occur in newborn animals which take the

FLUCTUATIONS IN BLOOD-UREA LEVEL DURING THE EARLY DAYS OF LIFE

No. of baby	Blood-urea (mg. per 100 c.cm.)			
	At birth	3–3½ days	6–6½ days	8 days or over
1	28·8	36·2	25·8	16·3
2	12 0	27·4	20 6	19·4
3	17·6	29·6	20·6	19·7
4	12·7	22·0	17·0	16·0
5	25·9	31·8	16·9	15·4
6	27·5	36·8	27·4	25·0
7	16·7	30·8	18·8	18 8
8	22·5	39 6	19·9	15·4
9	19·7	27·8	20·8	18·7
10	17·3	27·0	19 2	18·0

12	18·0	21·4	20 0	19·3
Average	18·9	29·1	19·7	16 8

those with hyperthyroidism, and thus must be accepted with reserve as an indication of a true diminution in incidence or severity of hyperthyroidism.

Table I shows that the number of patients with hyperthyroidism attending at our two clinics in the pre-war years 1936–39 was almost the same as in the war years 1941–44, being 77 and 76, or an average of about 19 cases a year. In 1940, when there was no malnutrition but much nervous strain, the number of cases was 14. The number of thyroidectomies done every year in the surgical department of the same hospital also remained about the same throughout the whole period. If these figures are expressed as a percentage of the total cases of all diseases dealt with, there is an apparent fall in incidence for 1940–44. But similar, though slighter, falls in percentage incidence occurred during the war in cancer of the stomach and disseminated sclerosis. It would therefore be rash to conclude that the fall in incidence of hyperthyroidism was real. What is certain is that the incidence of hyperthyroidism did not rise.

There is some evidence that during the war years hyperthyroidism was less severe. Table II shows that the B.M.R. determinations done in the medical and surgical clinics in 1936–39 were on the whole higher than those of 1941–44. This difference is not statistically significant, but the frequency-distribution curve suggests that there was a genuine change. A general decrease in the severity of hyperthyroidism might be related to malnutrition, especially to lack of protein. According to Wegelin (1926) and Paal and Kleine (1933), a diet rich in protein induces hyperplastic changes in the thyroid, whereas a diet poor in protein, or starvation, has the opposite effect. Similar evidence has been produced by Divry (cited by Brull et al. 1945). That severe malnutrition lowers the B.M.R. of otherwise normal persons is known, and during the famine in Belgium Govaerts and Lequime (1942) showed that in such cases the B.M.R. might fall 40–50% below normal. There is, however, another possibility. During the occupation the population consumed large amounts of vegetables of the brassica family, and these contain substances allied to thiourea (Kennedy 1942).

TABLE II—BASAL METABOLIC RATE IN HYPERTHYROIDISM

Basal metabolic rate (+ %)	No. of patients	
	1936–39	1941–44
0– 10	4 (*4·5%*)	8 (*8·6%*)
11– 20	12 (*13·5%*)	18 (*19·3%*)
21– 30	24 (*27·0%*)	25 (*26·9%*)
31– 40	11 (*12·4%*)	18 (*19·3%*)
41– 50	5 (*5·6%*)	11 (*11·8%*)
51– 60	10 (*11·2%*)	7 (*7·5%*)
61– 70	11 (*12·4%*)	4 (*4·3%*)
71– 80	6 (*6·7%*)	1 (*1·1%*)
81– 90	4 (*4·5%*)	1 (*1·1%*)
91–100	2 (*2·2%*)	—
Total	89	93

SIMPLE GOITRE

Cases of simple goitre have been observed only in the outpatient clinic. Table III shows the numbers of such patients attending in 1936–44. Both the absolute number and percentage incidence rose: the number from an average of 13 per annum in the pre-war years to 30 per annum in the war years; the percentages from 16% to 26%. These differences are statistically significant. The incidence of simple goitre has increased at all ages, particularly in the age-group 15–25 years.

TABLE III—INCIDENCE OF SIMPLE GOITRE

Year	No. of cases	Percentage of total new *patients*	Year	No. of cases	Percentage of total new patients
1936	11	13·5	1940	9	25·0
1937	13	10·5	1941	21	23·6
1938	14	14·0	1942	30	40·5
1939	14	20·0	1943	29	22·7
			1944	40	24·7
Total .	52	16·0	Total	120	26·0

Simple goitre can be produced experimentally by *lack of iodine (Marine 1935)*, by *interference with* the synthesis of the thyroid hormone by such preparations as thiourea, and perhaps by impairment of oxidative processes in the peripheral cells by means of substances like methyl cyanide. Brussels is located in a non-goitrous country, 80 miles from the sea. There is no reason to believe its population lacks iodine; if they did, goitre should have been prevalent before the war. It is possible that the lowered metabolism associated with severe malnutrition may, on the analogy of methyl-cyanide poisoning, have stimulated a hyperplasia of the thyroid.

Another possible explanation is that here again the increased incidence may be related to the heavy consumption of brassica vegetables. A diet rich in these is known to be goitrogenic in animals (Chesney et al. 1928, Marine 1935), and Kennedy (1942) showed that this may, at least in part, be related to their containing allyl-thiourea, which, in common with other compounds containing a thiourea grouping, produces simple goitre. Observations on closed communities forced to subsist on such diets in other parts of Belgium strongly suggest that simple goitres can be produced in this way.

MYXŒDEMA

The lowered metabolism of malnutrition might have been expected to raise the incidence of myxœdema. Our figures are too small for us to form any opinion on this point, though they show that in 1936–39 there were 3 cases, whereas in 1941–44 there were 11. But there are reasons for doubting whether starvation alone can produce myxœdema. By such means the B.M.R. can be lowered to −40% or even to −50%, but the cases show none of the characteristic clinical signs of myxœdema (Govaerts and Lequime 1942). The microscopical appearance of the gland in myxœdema is characteristic, and the glandular tissue remaining shows signs of temporary stimulation followed by degeneration (Bastenie 1944). In death from starvation, on the other hand, we have observed that the histology is that of the normal resting gland. Whether malnutrition may precipitate *incipient myxœdema into the full clinical syndrome* is another matter, on which no opinion can be expressed.

SUMMARY

The number and severity of cases of thyroid disease observed at the St. Pierre Hospital, Brussels, in the years *before* and *during* the German occupation have been compared.

The incidence of hyperthyroidism did not increase and may perhaps have decreased; and its severity probably diminished.

There was a significant increase in the incidence of *simple goitre*, especially in adolescents and young adults.

No opinion can be expressed about *the incidence of* myxœdema, save that starvation alone *does not produce* it.

There was no evidence that psychogenic factors influenced the incidence of diseases of the thyroid.

minded."' Encephalomyelitis is not uncommon in Uganda, Muwazi and Trowell (1944) seeing 20 cases in a series of 269 neurological cases. Though the pathology has not been worked out, these cases appear to be due to both myelinoclastic and polioclastic viruses. Disseminated sclerosis has only been reported in Africans by Sharp (1938), and very considerable doubt has been thrown on this diagnosis, Gelfand (1944) suspecting them to be cases of encephalomyelitis. The factors influencing the rarity of demyelinising diseases in Africans are completely obscure; but, if demyelinisation is associated with dietetic deficiencies, it should commonly be seen in Africans.

I am indebted to Miss M. Laing, M.B.E., S.R.N., for the history of these cases; Dr. P. W. Hutton, specialist physician, Mulago Hospital, for his advice; and the Director of Medical Services, Uganda, for permission to publish

DISEASES OF THE THYROID GLAND IN OCCUPIED BELGIUM

PAUL A. BASTENIE
M.D. Brussels
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF BRUSSELS AT BRUGMANN HOSPITAL

IT is commonly held that the thyroid gland reacts both to nervous and to nutritional strains, and that thereby abnormal states may be produced. Both these strains have been operative in Belgium since the German occupation in May, 1940: the nervous as the result of invasion, battles, air-raids, and inquisition by the enemy; the nutritional through restricted food-supplies.

It therefore seems worth while to record the changes observed in the nature and incidence of diseases of the thyroid gland during that period and to see if these can be correlated with environmental factors. Such an inquiry seems the more possible because the nervous and nutritional strains varied independently of each other. Nervous strain was present as a background throughout; the food situation varied significantly from the early to the latter part of the occupation.

The *food situation* during the war fell into two periods. During the first, which lasted from the end of 1940 to the middle of 1942, the rations supplied about 1300 calories, consisting of 250 g. of carbohydrates, 20 g. of fat, and 48 g. of protein, of which only 12·5 g. was animal protein. Vegetables were, however, available on the free market, and large quantities of kohlrabi, cabbages, &c., were consumed. In the second period food shortage was less severe. Official rations rose to 1400 calories a day, and a black market—of which an enlightened account has been given by Ellis (1945)—was organised. A survey carried out in January, 1945 (Bastenie et al. 1945), revealed that cereals, potatoes, and vegetables formed an abnormally high proportion of the diet, which was deficient in calories, fats, animal protein, calcium, and riboflavine. The gross figures showed an average intake of 2100 calories—43 g. of fat and 66 g. of protein, of which 19 g. was animal protein.

Signs of malnutrition appeared during the first period. Loss of weight to the extent of 20–30% of the initial weight was usual; there was a general fall in plasma-protein and blood-urea concentrations; many cases of hunger œdema appeared (Govaerts and Lequime 1942, Govaerts and Gregoire 1941, Brull et al. 1945); and there was an increased incidence of infectious diseases, especially tuberculosis. In the second period hunger œdema disappeared, and the tuberculosis-rate regressed, but the weight remained at its previous low level or rose only slightly, and there was a general complaint of muscular weakness, easy fatigability, and inertia.

Thus the environmental factors under consideration group themselves in three periods: in 1940 there was acute nervous strain but no malnutrition; in 1941 and 1942 acute malnutrition but rather less nervous strain; and in 1943 to 1945 chronic malnutrition but heightened nervous strain consequent on the recurrence of intensive air-raids and battle.

MATERIAL

The material on which the following observations are based was drawn from the university medical clinic of Prof. P. Govaerts at the St. Pierre Hospital, Brussels, and from the endocrine outpatient clinic of the same hospital. For comparison some data from the surgical clinic of Prof. R. Danis at the same hospital have been included. The patients attending all these departments are drawn from the lower classes and were exposed throughout, without special mitigation, to the nervous and nutritional strains outlined above. They came from the environs of Brussels, a district where goitre is not normally endemic. Reference has already been made to the general increase of ill health during the occupation. The effects of this were seen in increased admissions and attendances at the hospital. A further factor swelling admissions to our hospital was the requisitioning of other hospitals in Brussels by the enemy. The only major population change which is known to have taken place is that in 1944 many young men were deported by the Germans, but the admissions to the medical clinic in 1936–44 show that the age-distribution did not change appreciably. Due consideration must be given to these factors in comparing the incidence of any illness before and during the occupation. The changes in incidence of thyroid disease are recorded below as a percentage of total admissions, but more weight should perhaps be attached to the absolute number of cases.

HYPERTHYROIDISM

Attention was first drawn to the changing incidence of diseases of the thyroid by Brull (1942), who found that the basal metabolic rate (B.M.R.) of all goitre cases sent to his clinic showed a steady decline from an average figure of +21·9% in 1939 to +6·6% in 1942. But this study makes no distinction between simple goitre and

TABLE I—INCIDENCE OF HYPERTHYROIDISM

Year	Endocrine outpatients clinic		Medical clinic	
	No. of cases	Percentage of total new patients	No. of cases	Percentage of total admissions
1936	9	11·1	10	0·55
1937	13	19·7	12	0·65
1938	12	12·0	6	0·32
1939	8	11·5	7	0·39
Total ..	42	13·3	35	0·49
1940	3	8·3	11	0·43
1941	9	10·1	7	0·18
1942	5	6·7	12	0·28
1943	16	12·5	6	0·17
1944	9	5·5	12	0·38
Total ..	39	8·5	37	0·25

In 1941–44 the number of patients attending either clinic was about double the number attending in 1936–39.

The analyst—the personal element—is finally eliminated. We are left with a series of essentially disciplinary exercises for the tackling of which considerable narcissism would be required, combined with an intellectual watchfulness rarely found in those who need help. He cogently contrasts these exercises, to their advantage, with Yoga, Christian Science, and Couéism. But every Yogi knows how rare it is to find someone capable of understanding Yoga. Is this chemico-mechanical affair with its vague vital principle really worth working for? For most people it is not. The ordinary man incorrigibly remains a person.

Early Ambulation and Related Procedures in Surgical Management

DANIEL J. LEITHAUSER, M.D., F.A.C.S., chief of surgery, St. Joseph Mercy Hospital, Detroit, Michigan. Springfield, Ill.: Charles C. Thomas. London: Baillière. 1946. Pp. 232. 25s.

LEST there should be any misunderstanding about the meaning of "early ambulation," the dust-cover of this book explains that 810 of the 2017 cases under review were out of bed three or four hours after operation. "Early" is thus no exaggeration, and this is the more surprising since Dr. Leithauser advocates spinal anæsthesia. He thinks it is the patient's "natural instinct to get up and move about after an operation" and that only outworn tradition and the wicked surgeons and nurses prevent him. At least in this country, surgeons appreciate the importance of early and unrestricted movement in the prevention of atelectasis and thrombosis; but the advantage of performing such movement in the erect rather than the recumbent position is debatable. Dr. Leithauser's series of cases lends support to his method: atelectasis, thrombosis, and embolism are, he says, almost eliminated, bedpans are dispensed with, and the period in hospital is enormously reduced, the average stay of 795 cases of acute appendicitis being only two days. (These were all private patients whose homes were presumably more suitable for their early return than those of hospital patients in this country.) He suggests that râles, indicating the presence in the lungs of secretion requiring expulsion, were often only apparent when the patient stood up and consequently dislodged some mucus, and he believes that coughing is much more effective in the upright position. The reader, even if he does not accept all these contentions, will probably be sufficiently stirred by Dr. Leithauser's confidence to want to put some of them to the test.

Chemical Methods in Clinical Medicine

(3rd ed.) G. A. HARRISON, M.D. Camb., reader in chemical pathology in the University of London at St. Bartholomew's Hospital. London: J. & A. Churchill. 1947. Pp. 630. 40s.

PAST editions of this standard work have done much to bring the chemical laboratory into close contact with the ward, and to stimulate the interest of pathologists and clinicians in each other's activities and in the application of the latest scientific knowledge to both treatment and diagnosis. It is not only a guide to laboratory knowledge and technique, and to the interpretation of biochemical results, but also, in Dr. Harrison's own words, "my own journal," carrying descriptions of many useful inventions, as well as observations and interpretations which will not be found elsewhere. The new edition besides being thoroughly up to date contains much new material—on pigmentation, sulphonamides, and new analytical procedures and functional tests.

L'ostéosynthèse au clou

R. SOEUR, chirurgien-adjoint des hôpitaux de Bruxelles. Paris: Masson. 1946. Pp. 132. Fr. 325.

M. Soeur has developed the idea of intramedullary nailing for shaft fractures of all the long bones, using c-shaped steel nails, inserted through the medullary canals. In his hands the results have been good, and the [illegible] emboli and sepsis—have not [illegible]. But on the face of it the method will not appeal to those pleased with the results [illegible] treatment. The most interesting [illegible] a short digression dealing with [illegible]s. Here he claims, and illustrates [illegible]vels's angles are caused by a beak of bone on the under-surface either of the proximal distal fragment. If on the former, union is doubtful if on the latter, the fracture almost always heals.

A Study on Oxygen Toxicity at Atmospheric Press

WILHELM T. L. OHLSSON. Lund: Hakan Ohlsso Boktryckeri. 1946. Pp. 93.

THIS interesting little monograph is mainly résumé of investigations in which the author tried determine the effect of the inhalation of 80–90 % oxygen at atmospheric pressure on rabbits previously exposed to either phosgene or blast injuries. In addition, the effect of this concentration of oxygen was investigated in healthy human subjects. He concludes that the pulmonary damage caused by oxygen in high concentrations is not produced by a direct irritant effect on the lungs, but by a disturbance in the blood carriage of carbon dioxide. He also believes that oxygen only becomes harmful when the supply exceeds the demand. A reasonably full review of the literature provides a useful background to his observations and all they imply. While the case presented is by no means watertight, it contributes to our knowledge of the subject, and will interest all concerned with the therapeutic use of oxygen.

Experiences with Folic Acid

TOM D. SPIES, M.D., associate professor of medicine, University of Cincinnati. Chicago: Year Book Publishers. London: H. K. Lewis. 1947. Pp. 110. 21s

THIS is a useful account of what has been learnt about folic acid since the therapeutic use of the synthetic substance began about 18 months ago. The history of the investigations leading up to the discovery of folic acid is outlined, but the greater part of the book is concerned with the diagnosis and selection of suitable cases, and with the effect folic acid had on them. The necessity for correct diagnosis is rightly stressed again and again but the detail is transatlantic in luxuriance; for instance the record of the size of the ears, and the 36 investigations listed for every case of sprue, show what is possible to those who have no difficulties over man-power or equipment. All the same, among the detail the critical points are always observed and clearly noted. It is stated that 218 cases have been treated, including 78 of Addisonian pernicious anæmia, 5 of cirrhosis of the liver (only 1 responded), and 8 of an undefined entity "nutritional leukopenia"; the rest were mostly nutritional macrocytic anæmia and sprue. The results of treatment are well described and illustrated, sometimes in colour. Spies does not minimise the difficulties and puzzles that folic-acid treatment has raised. He notes that the results in pernicious anæmia were no better than with liver, and gives figures confirming that lesions of the central nervous system are unaffected and may progress or even make their first appearance while the patient is being maintained on folic acid. He therefore agrees that folic acid is neither the most effective nor the safest remedy for pernicious anæmia; it is in the treatment of nutritional anæmias that it will be most useful. The part played by folic acid in hæmopoiesis, including the place of the conjugates, is briefly discussed; but Spies thinks that there is insufficient evidence as yet to say any more than that it functions as part of an enzyme system that is disturbed in these diseases. Folic acid is neither the extrinsic nor the intrinsic factor of Castle.

Electrocardiography (2nd ed. London: H. Kimpton. 1946. Pp. 881. 60s.). **Exercises in Electrocardiographic Interpretation** (2nd ed. London: H. Kimpton. 1946. Pp. 288. 30s.).—Dr. L. N. Katz has made the second edition of his *Electrocardiography* considerably larger than its predecessor, with 250 new tracings. New matter is included on the normal cardiogram, on the patterns of axis shift and right and left heart strain, and on coronary disease, which is very well illustrated; there is also a new section on cardiograms simulating the coronary pattern. With its perfect black-and-white tracings and lucid style this book remains an outstanding exposition of cardiology, though too detailed for the average beginner. The second edition of the companion volume has been enlarged and revised to conform with the larger volume, and reaches the same high standard.

The observed changes of incidence and severity are hought to be related to the quantity and quality of the liet, especially the increased consumption of cabbages nd related vegetables which contain substances of the hiourea group.

GUMMA OF THE THYROID

A. H. BARBER
M.A. Oxfd, M.B. Birm., M.R.C.P., F.R.C.S.
SURGEON, BOUNDARY PARK GENERAL HOSPITAL AND THE ROYAL INFIRMARY, OLDHAM

GUMMA of the thyroid is extremely rare, with a very variable clinical picture. Williams and Steinberg[1] concluded that women were more often affected than men, and that the gumma might result from either hereditary or acquired syphilis. They found that there was usually no disturbance of thyroid function; but, if there was, it was myxœdema rather than hyperthyroidism, and symptoms of mechanical interference and confusion with carcinoma sometimes arose.

A woman, aged 37, had a slight swelling in her neck in October, 1939. She did not feel ill but sometimes felt breathless. She was bronchoscoped, but nothing abnormal was found. I first saw her in August, 1942. At that time her neck was swollen, and the thyroid, which was slightly enlarged, felt very hard. There was a little exophthalmos, and her pulse-rate was 120 per min., with fibrillation. She appeared to be a case of thyrotoxicosis, but the thyroid was unusually hard, suggesting carcinoma. She was admitted to Boundary Park General Hospital, Oldham, for rest and observation, and improved slightly on Lugol's iodine. In December she began to have difficulty in swallowing and became slightly hoarse. It was felt that an exploratory operation was justified.

Operation (Dec. 17, 1942).—The thyroid gland was found to be extremely hard and densely matted to the surrounding structures. It was impossible to do anything except remove a portion for section, the macroscopical diagnosis being carcinoma of the thyroid. Immediately after the operation she felt much better, her pulse-rate dropped from 120 to 90 per min., and she was discharged on Dec. 30.

A little later she developed two ulcers in the scar and others on the right thigh and left shoulder. These were undoubtedly gummata and gave the clue to the condition of the thyroid. Dr. William Susman, of Manchester University, who kindly examined the section, reported: "The lesion in and about the thyroid is a gumma. The gland also shows chronic thyroiditis, with loss of typical thyroid structure. The gland is adherent to some neighbouring voluntary muscle."

The patient was given large doses of pot. iod. and liq. hydrarg. perchlor. and made a complete recovery. At the time of the operation she weighed 6 st., and her weight 2½ years later was over 9 st.; the exophthalmos had disappeared, the heart-rate, though rapid, was regular, and she had no obstructive symptoms whatever. The Wassermann reaction however was still positive.

There are several unusual features about this case. There were undoubted symptoms of hyperthyroidism with some tracheal obstruction, but the thyroid, though only slightly enlarged, was unduly hard. It seems that in such circumstances a Wassermann reaction and an exploratory operation should always be done. In this case, had she not been operated on, gumma of the thyroid would not have been thought of. Crotti[2] has already emphasised this point; he urges that, since syphilis of the thyroid has often been taken for a malignant tumour, whenever malignancy is suspected the possibility of syphilis should be investigated.

Reviews of Books

Child Health

Editors: ALAN MONCRIEFF, M.D., F.R.C.P.; W. A. R. THOMSON, M.D. London: Eyre and Spottiswoode for *The Practitioner*. 1947. Pp. 254. 14*s*.

FOR over fifty years there have been good books on the diseases of children, but until recently there was no convenient manual for the increasing number of doctors who spend their days in supervising the health of children, in the maternity hospital, the welfare centre, or the school. Two of the new professors of child health have produced such books during the past year, and now Professor Moncrieff and Dr. Thomson give us a third, most of whose chapters have already been published as articles in *The Practitioner*. The authors of the various sections have been well chosen; they write of what they know, and the result is a practical book built on first-hand experience. Rather over half of them are employed by local authorities, who are responsible for most of the child-health services. The book tells about the lay-out of a child-welfare centre, the home treatment of the blind baby, the vitamin and mineral requirements of the infant, the establishment of respiration, and what happened when typhus patients were distributed through the wards of the Edinburgh Royal Infirmary. The print is clear, the paper only slightly transparent, the binding attractive, the index detailed (even diverse: "*torticollis*" gives one reference, "wry-neck" another). This compact compendious book is negligible as an anatomy of health (it does not even contain tables of growth), but as a handbook about the prevention of illness and the care of the handicapped child it will be found very valuable.

Ego-Hunger and Aggression

F. S. PERLS, M.D., captain, S.A.M.C. London: Allen & Unwin. 1947. Pp. 273. 12*s*. 6*d*.

EVEN in Dr. Perls's most abstract discussions it is easy to perceive the wealth of clinical experience which his fine critical mind has not ceased to align with his desire to think consistently. But the need to argue his own philosophico-psychological standpoint, to disagree here and there with Freud, to state his own neo-freudian psychopathology as well as make his own contribution to psychotherapeusis—and all in the same book—tend to cloud the issues. The reader requires a clear-cut statement of either Dr. Perls's therapeusis, or of his philosophic standpoint, or of his argument with Freud: the three-in-one make for obscurity.

On the way to his philosophic standpoint of belief in the Creative Present, Dr. Perls criticises *mind-body* parallelism, and discards subjective observations except in so far as they can be restated in objective terms. Preservation of the organism demands ego-feeling—the consciousness of boundary—but there is no "self." He discards libido in favour of a rather vague Bergsonian *élan vital* and a striving after fulfilment of "the figure background" need, the gestalt.

Freud gave to Dr. Perls what classical philosophy, he says, had withheld. But Freud was not a philosopher. He did unintentionally provide a near-religion for some (but he did not so regard it himself), and in common with others he implied a philosophy of determinism, the negation of personal value. Dr. Perls also negates this value, though differently: the objective, by definition, is non-personal. He disposes arbitrarily of religion, diagnosing God as a projection of man's omnipotent self. The suspicion arises that Omnipotence has been ousted by Omniscience and God has merely become impersonal.

In his underlying philosophy lies the weak point in the therapeutic technique described in the last section.

ARRESTING

The Male Climacteric

BY PERORAL HORMONE THERAPY

The mental fatigue and diminished bodily energy which characterise the male climacteric respond readily to male hormone therapy in the form of ORAVIRON (British Schering brand of methyl testosterone in tablet form). Depression and nervous instability are eliminated, and the general condition, both mental and physical, shows a steady improvement.

'ORAVIRON' is presented in tablet form in the following sizes:

TUBES *of 20 × 5 mg tablets* TUBES *of 20 × 10 mg tablets*
BOTTLES *of 100 × 5 mg tablets*
BOTTLES *of 100 × 10 mg tablets*

ORAVIRON

Fully descriptive literature gladly sent on request.

BRITISH SCHERING LTD. 167-169 Great Portland Street, London, W.1

53c

OTITIS MEDIA

AURALGICIN one

DDA

DECONGESTION OSMOSIS WITH REMEDIAL ANALGESIA

DECONGESTION SUCCESSFULLY ACHIEVED by the addition of Ephedrine Sulphate which acting in synergy with the other ingredients produces shrinkage of the mucosa, promotes drainage from the middle ear and a rapid control of pain. The bactericidal constituents of Auralgicin cover a wide range of micro-organisms including those likely to be present in otitis media, thus avoiding the danger of masking.

Each ml. contains :

Phenazonum	0.050 g.
Papaveretum	0.025 g.
EPHEDRINE SULPH.	0.01 g.
Chlorbutol	0.010 g.
Pot. Hydroxyquinolin Sulph.	0.001 g.
Glycer ad 1 ml.	

FOR EXTERNAL APPLICATION

BENGER'S LTD. HOLMES CHAPEL, CHESHIRE

Two-fold action

I. NUTRITIONAL SUPPLEMENT

'Taka-Bexin' contains important members of the vitamin B complex, together with vitamin C which is intimately associated with the vitamin B complex in its therapeutic applications.

2. DIGESTANT

'Taka-Bexin' contains Taka-Diastase, a potent diastatic enzyme capable of promoting adequate starch digestion.

'TAKA-BEXIN'

CAPSULES

Indicated in conditions in which deficiencies of vitamin B complex and vitamin C may arise as a result of nutritional inadequacy, digestive disturbances or increased vitamin requirements. These conditions include anorexia, polyneuritis, pregnancy and lactation, febrile illnesses, hyperthyroidism, restricted diets and convalescence. Particularly useful in elderly patients and in those who need assistance in digesting the starchy foods predominant in present-day diets.

The initial dosage of 'Taka-Bexin' is two capsules three times daily just before meals. After ten days or two weeks on this dosage, one capsule three times a day may be sufficient. Supplied in bottles of 50 capsules.

Formula

Taka-Diastase	1 gr.
Vitamin B_1 (Aneurine Hydrochloride) ..	1 mgm.
Vitamin B_2 (Riboflavin)	1 mgm.
Vitamin B_6 (Pyridoxine Hydrochloride) ..	0·5 mgm.
Pantothenic Acid	0·15 mgm.
Nicotinamide	6 mgm.
Vitamin C (Ascorbic Acid)	15 mgm.

Inc. U.S.A., Liability Ltd.

tissue specificity—may, in last analysis, have been derived from the genetic system of host cells. In his most interesting lecture CRAIGIE took us step by step through the various forms of latency until he reached what he termed "cryptic" infection—that hypothetical state in which the virus has lost its cytoclastic properties and multiplies inside the host cell at just the tempo that will ensure there being enough virus to maintain infection when the cell divides. Such an infection would defy detection by the usual methods. Although, as CRAIGIE said, cryptic infection, in the case of viruses affecting man and animals, is still in the realm of hypothesis, recent work with the bacteriophage lends it support.

He instanced work of his own on an avirulent variant of the type II Vi phage, the gamma agent. This gamma agent is carried by all type D_1 strains of *Salmonella typhi*, and seems to be able to multiply along with the bacterium, without obvious harm to the latter, over long periods. Only with difficulty can the gamma agent be demonstrated as a bacteriophage, and it is hard to maintain, being lost from time to time, or rather (as CRAIGIE suggests) returning to the fully cryptic avirulent state. Infection with this gamma agent has definite effects on its bacterial host, making it either resistant to Vi phages or susceptible only to D_1 phage; it is possible also that infection may result in the loss of H and O antigens.

Discussing the bearing of latent or cryptic infection on the basic problem of cancer, CRAIGIE pointed to the similarity between the hypothetical cryptic virus and the plasmagenes—those hypothetical cytoplasmic particles which some biologists are postulating to explain the inheritance of cytoplasmic traits—and said that some virus workers are prepared to identify certain of the more lowly viruses with plasmagenes. But he went on to speak of the dilemma which acceptance of this view entails. Though there are differences between, on the one hand, the viruses of the psittacosis-lymphogranuloma group or the pock viruses, and on the other hand the very small viruses of poliomyelitis and foot-and-mouth disease, there is no indication that these differences betray a fundamental difference in their nature.

T. M. RIVERS, alone almost among virus workers, seems to hold that the agents now grouped together as viruses may be heterogeneous, and that while the large viruses like psittacosis are probably micro-organisms the very small and simple viruses are non-living things. The large majority would agree with both CRAIGIE and BURNET when they say that the viruses present an unbroken series, proceeding from the smallest and simplest to the largest and most complex, and from them to the rickettsias, and that there is no sign of fundamental difference between the members of this series. If, then, one were to agree that some of the less complex viruses are derived from genes, it would presumably follow that the more complex ones have evolved from them; and one would have to consider when, how, and why the naked gene decided to clothe its nudity. More acceptable is the hypothesis, propounded independently by GREEN[10] in America and LAIDLAW[11] in this country, that viruses have arisen from higher forms of micro-organisms by a process of progressive adaptation to a parasitic existence, in which the parasite is finally reduced to a bare nucleoprotein molecule, capable of self-replication but relying on the host cell entirely for the necessary materials a energy. It is this hypothesis which BURNET adopts, since "there seems to be no visible alternative", and, having accepted viruses as micro-organisms adapted to a parasite existence, and capable, like other living things, of producing variants—in point of fact highly endowed in this respect—he proceeds to consider the evolution of virus disease.

Human virus infections, he thinks, must have been derived from similar conditions in animals, because, for a parasitic micro-organism to survive, there must be sufficient opportunity for the transfer of infection; and until man changed from hunting to cultivation of the soil, and took up communal life, the chances of transfer of infection were too small to make him a suitable host for the continued existence of a virus. Epidemic typhus has arisen from rodent typhus by the adaptation of the causal rickettsia to the human body-louse; and in the chapter on psittacosis BURNET suggests that at the present time we are probably witnessing the adoption by psittacosis virus of man as a permanent host. (In some outbreaks of infection with viruses of this group the virus has passed readily from man to man and there was no evidence that the infection came from birds.) But besides change in the virus, leading to change in an infectious disease, one may have change in the other partner, the host, though this is probably a less important factor. Host change is usually immunological, but that it may be social is suggested by BURNET when discussing the epidemiology of poliomyelitis. This disease, from being essentially one of the early years of life, infection coming from the adult, is changing to one in which the main incidence is in children of school age, infection passing from child to child and the adult escaping. This change in epidemiological pattern is seen especially in those countries—North America, Australia, and Scandinavia—where social hygiene and sanitation have reached higher levels than elsewhere, and BURNET suggests that these factors may be responsible for the change.

Although, in their evolution, virus diseases show many fluctuations, the virus variants of increased virulence must tend to eliminate themselves, since they are too destructive to their hosts. Hence the general tendency is towards an equilibrium in which host and parasite are so adjusted to one another that infection is widespread but the host little incommoded. The unique example of this state in virus diseases is herpes simplex.—This, in very broad terms, is the argument which runs through BURNET's fascinating monograph.

War, Famine, and Goitre

IT might be expected that the stresses of war would lead to an increase in toxic goitre. In neither of the two world wars, however, was a high incidence noted among the fighting troops; in fact toxic goitre remained a rare condition in the Army. Clinicians do not seem to have found any increase among civilians in the United Kingdom, though in the absence of statistical data an increase might not have been detected. The Registrar-General's figures for the deaths from toxic goitre do not suggest that the war had any appreciable effect on the mortality. Yearly deaths from this condition rose slowly and steadily from 1913 to 1936, and then declined at a

THE LANCET

LONDON: SATURDAY, JUNE 7, 1947

Viruses and Disease

BELIEF in spontaneous generation has died hard. In the 17th century its exponents were forced to admit that it was inapplicable to the larger living things, like mice and the larvæ of the blue-bottle fly; but when, in the earlier part of the last century, bacteria were discovered, many felt sure that here at least was a form of life which must arise spontaneously. The carefully planned experiments of PASTEUR and TYNDALL proved them wrong: bacteria were shown to arise from bacteria; they followed the normal reproductive process of like producing like. One might have thought then that the last had been heard of spontaneous generation. Yet with the discovery of filtrable viruses, and inquiry into their reproduction, this conception was reborn. In the years between the two wars much time was spent in discussing not only how viruses are generated but also whether they are alive, and the outcome was never quite decisive. Most of the workers concerned, however, came to the conclusion that, for all practical purposes, viruses behaved like autochthonous living things. After all, this had been tacitly assumed in every experimental transfer of a virus infection, and also in all our attempts to control virus diseases by the same preventive measures as have proved effective in controlling micro-organismal disease. The eradication of rabies from this country, the exclusion of rinderpest from Australia, and the considerable success achieved against foot-and-mouth diseases in Britain indicated that the assumption was well founded.

In his illuminating monograph, *Virus as Organism*,[1] F. M. BURNET treats of viruses from an ecological angle, considering how they "make a living" in the environment which nature and mankind have allotted them. He begins by discussing their reproduction, variation, and survival, and he points out that in the last two decades a great deal more has been learnt about them. We can measure them and have established that the larger ones can be seen by ordinary microscopy. The electron microscope has rendered visible the smallest viruses, and has revealed signs of a definite internal structure in large viruses such as vaccinia.[2] The large viruses have been shown, like bacteria, to be complex antigenically, and for some of them, including vaccinia,[3] there is reason to presume a chemical structure recalling that of a typical bacterium. The large viruses appear also to possess complex enzyme systems; of this we have direct evidence in the case of vaccinia virus,[4] while the sensitivity to sulphonamides exhibited by the viruses of lymphogranuloma venereum, inclusion blennorrhœa, and the mouse pneumonia of Nigg and Eaton is indirect evidence of the same thing. All this, and the fact that, whatever the environment in which they multiply, viruses breed true, leaves little doubt that they are extrinsic agents of micro-organismal nature, each virus particle being a direct genetic descendant of a similar particle. And yet, as BURNET says, some workers are reluctant to abandon the conception of viruses being derived from the cells of higher animals or plants; they suggest that viruses may be genes which, freed from their normal setting, have become capable of abnormal multiplication and survival by transfer from host to host. In his lecture on Latent Virus Infections, delivered before the Royal College of Surgeons on April 16, Dr. JAMES CRAIGIE, F.R.S., considered this possibility, particularly in reference to what he calls "cryptic virus infections"; and DOERR[5] in 1938 stoutly maintained that herpes virus is the product of deranged cells. Though we now know that DOERR's thesis is untenable, probably one of the most interesting chapters in BURNET's monograph is that in which the natural history of herpes is reviewed.

ANDREWES and CARMICHAEL[6] in 1930, and R. T. BRAIN[7] in 1932, observed that in adults the presence of herpetic antibody in the blood was related to a history of herpes; and the suggestion was made that sufferers from this condition were carriers of the virus. The time when they were first infected remained unknown until 1938, when DODD, JOHNSTON, and BUDDINGH[8] showed that aphthous stomatitis in young children was usually due to herpes virus. It was here that BURNET and his colleague WILLIAMS[9] took up the work. After confirming the American findings on the ætiology of aphthous stomatitis in children, they proved that this was in fact a primary infection, since herpetic antibody was absent in the acute phase of the disease but appeared during convalescence. From this they proceeded to a serological survey of herpetic antibody, using a more accurate method of titration than previous workers. Their results were of an all-or-nothing character: herpetic antibody was either absent or was present in high titre, and again its presence was related to affliction by herpes. Only the failure to isolate the virus from carriers prevented BURNET and WILLIAMS from completing the story, but enough evidence had been found to make it clear that herpes virus was an extrinsic agent and that infection with it, which commonly occurred in the second or third year of life, persisted after clinical recovery, leaving a carrier state which revealed itself by an attack of symptomatic herpes when some factor depressed the host's resistance and allowed the virus temporarily to get the upper hand. These facts are doubly interesting, because they give us a picture of an infectious disease which has reached a state of equilibrium—in which host and parasite are so well adjusted to one another that the infection can be widely disseminated with little detriment to the host.

If, however, we can dismiss with confidence DOERR's hypothesis of the origin of herpes virus, we may not feel quite so sure about the claim that some other viruses—particularly those concerned in the production of tumours, with their very strict host and

two months of beginning folic-acid treatment. VILTER et al.[5] reported that, out of 24 cases of pernicious anæmia treated with folic acid and observed for a year, 4 developed pathological signs in the nervous system, and no improvement was obtained by increasing the dose of folic acid up to as much as 500 mg. daily. Both reports agree that improvement is obtainable by giving liver or desiccated stomach extract; WILKINSON prefers the latter. Another finding is the tendency for increasing doses of folic acid to be required to maintain a normal blood-count. At first the dose was cut down to 5 mg. daily or less; in time the blood-counts of these patients began to fall and the dose was raised; but after an interval the fall began again WILKINSON had 2 and VILTER et al 3 such patients needing increasing doses over a year, and it may well be that more such cases will be noted as time goes on. WILKINSON concludes that folic acid is "neither the best nor the cheapest form of treatment for pernicious anæmia, whether neurological signs are present or not," and SPIES[1] says that "liver extract is the safest and most effective therapy for the routine treatment of pernicious anæmia." Folic acid will retain a limited place in the treatment of this disease, for it can be given parenterally to obtain a rapid initial response in a critically ill patient and it will be useful temporarily in patients who are sensitive to liver extracts, though such patients should be desensitised or given desiccated stomach as soon as possible. No advantage is to be gained from "blunderbuss" preparations containing added folic acid. It is clear that in pernicious anæmia folic acid will do nothing that liver—or desiccated stomach—will not do somewhat better; therefore added folic acid is merely wasted and may cover up an inactive liver preparation.

In nutritional anæmias, including pernicious anæmia of pregnancy, nutritional macrocytic anæmia, and the sprue syndromes, folic acid can be used with impunity since there is no risk of spinal-cord disease. SPIES's account of the striking effect of folic-acid treatment in this group of diseases in the southern U.S.A. and Cuba is very convincing, and reports from other parts of the world on nutritional macrocytic anæmias—e g., that of DAS GUPTA and CHATTERJEE[6] in India—are equally good. The results in sprue vary because it is not clear that the diseases met with are comparable. The "sprue" of Cuba and Puerto Rico is a failure of fat absorption from the stools, causing diarrhœa with a megaloblastic anæmia and occurring among natives who have been undernourished for years; folic acid clears both the anæmia and the diarrhœa and improves the stools. The sprue of India and the Far East is a syndrome affecting foreigners with normal nutrition, and the non-tropical sprue and cœliac syndrome of temperate climates appears also in persons who are not significantly undernourished; signs of malnutrition develop during the course of the disease as a result of the partial failure of intestinal absorption. It is therefore not surprising that the results with Asiatic and non-tropical sprue are different. MANSON-BAHR and CLARKE[7] reported a favourable response to folic acid in a typical relapse case of sprue; DAVIDSON et al.,[8] in 4 similar cases, found that though the diarrhœa was improved the blood state was unaffected; MORRISON and JOHNSTON[9] had excellent responses in 2 soldiers who developed sprue after their return to the U.K. from India, but in 2 relapsed cases there was no blood improvement In non-tropical sprue (idiopathic steatorrhœa) DAVIDSON et al. noted a moderate improvement in 3 cases, WILKINSON had 1 patient showing an excellent blood and intestinal response, 1 with moderate, and 2 with little improvement. Reports on cœliac disease are similarly variable. Every case of these syndromes that responded to folic acid at all had a megaloblastic marrow. Thus in nutritional macrocytic anæmia—including West Indian sprue—if there is a megaloblastic marrow a good response from folic acid can be predicted. Other forms of macrocytic anæmia may respond if there is a megaloblastic marrow but not if the marrow is normoblastic. It is in nutritional anæmias that folic acid is likely to be most useful, and since such anæmias are widespread in the tropics this is a sufficiently important application.

What part does folic acid play in hæmopoiesis? It is neither the extrinsic nor the intrinsic factor, for it is possible to get responses with liver extracts that contain only traces of folic acid. Folic acid exists in nature in several forms that differ according to the number of glutamic-acid groups in the molecule. Thus, the synthetic acid—which is the same as that obtained from liver and from yeast—contains one glutamic-acid group; another form contains seven[10]; and the "fermentation acid" three.[11] The synthetic acid is known as "free" and the others as "conjugated" folic acids. When free folic acid is given to a patient with pernicious anæmia, or to a normal person, a good deal is excreted in the urine. When conjugates are given, normal people excrete free folic acid, but pernicious-anæmia patients excrete hardly any until they are given liver extract when there is a large excretion. It has been reported that folic acid conjugates do not produce a hæmopoietic response in pernicious anæmia.[12] [13] Hence, it might appear that the defect in pernicious anæmia is inability to release folic acid from its naturally occurring conjugate forms in food. DAVIDSON and GIRDWOOD[14] therefore suggested that liver extracts act in virtue of a "liberating factor" that allows free folic acid to be formed from conjugates stored in the body and so initiate the hæmopoietic response. The American workers, however, do not subscribe to this attractively simple theory, though it had occurred to them; there are difficulties. SUAREZ et al.[15] found that West Indian sprue responds to treatment with conjugates, and that some pernicious-anæmia patients also respond. SPIES[1] holds that the doses of conjugates used in the negative reports were not large enough; lately he and his colleagues[16] have reported successes with various conjugates in pernicious anæmia as well rather sharper rate. When the figures from 1913 to 1945 are plotted there is no suggestion that either of the two major wars made the slightest impression on the curve.

The experiences of enemy-occupied Europe should be more illuminating, though the stresses to which the inhabitants were subjected were different from ours and there was also the complicating factor of famine. So far, the only information has come from Denmark, where Meulengracht[1] reported a sudden increase in thyrotoxicosis during 1942; and from Belgium, where Professor Bastenie, in this issue, records that there was no apparent increase. Meulengracht's account only takes us up to the end of 1942, and a final assessment must await the publication of data for subsequent years His evidence was derived from admissions to his own department, supplemented by figures for all the hospitals in Copenhagen. There was a slow rise in the number of cases of thyrotoxicosis from 1933 to 1941, with a slight fall in 1939 and 1940, probably related to a fall in all admissions to hospital. But in 1942 the number of cases seen in Meulengracht's own department rose to 118, from 34 in the previous year. Other clinicians in Copenhagen seem to have had a similar experience. Meulengracht discussed the possible statistical fallacies, and concluded that both the slow rise during 1933–41 and the abrupt increase in 1942 were real phenomena though probably independent. He could not explain the rise and was reluctant to ascribe the 1942 "epidemic" to the emotional disturbances of war, because he found no abnormal incidence of mental crises in the histories of his patients, and there seemed to be no evidence of a similar increase in the other countries involved in the war.

Bastenie shows that the number of cases of toxic goitre treated at the St. Pierre Hospital, Brussels, remained relatively constant before and during the war. His data are open to criticism in that they are derived from a single hospital Not only may the population from which the cases were drawn have changed in size and composition, but cases may also have been diverted to or from the hospital by reason of such factors as the acquirement of a reputation for the treatment of toxic goitre, or fluctuations in available accommodation. Bastenie is plainly aware of these possible fallacies, and he makes it clear that the total number of patients treated for all diseases in the hospital did in fact rise during the war years. For this reason changes in the percentage incidence of toxic goitre relative to all medical admissions cannot be admitted as evidence; Bastenie rightly takes the absolute number of cases of toxic goitre as being a more reliable index, and these do not seem to have changed significantly His second point is that there was an apparent decline in the severity of the toxic cases (as judged by the B.M.R. figures) during the war. By itself this is slender evidence; but it does agree with his third observation, that there was an apparent increase in the number of cases of simple goitre. The cause of this is unknown but it might well be the result of famine, as Bastenie suggests. It may be that the lowered metabolism of starvation stimulates the pituitary to produce more thyrotropic hormone; but, as he points out, there is no evidence of thyrotropic stimulation in cases of death by starvation. His second explanation is more plausible. Because other foodstuffs were not easy to obtain the population of Belgium tended to eat more and more vegetables of the brassica family; and vegetables of this type are known to contain goitrogenic substances of the thiourea group. If the increase in simple goitre in Belgium was in fact comparable to the "cabbage" or "rape-seed" goitre of animal experiments, a reduction in severity might be anticipated in cases of toxic goitre on the same diet. Such patients would, in effect, be treating themselves on the most modern lines. If this is the correct explanation it leaves open the possibility that there was an actual increase in thyrotoxicosis in Belgium during the war, which was masked because the population was being simultaneously dosed with thiourea compounds taken in the diet. No such masking effect would be expected in Denmark, where the food situation was much better than in Belgium throughout the war.

Thus it may be possible to reconcile the findings of Meulengracht and Bastenie. But the foundation of fact on which these speculations are built is exceedingly slight and badly needs supplementing from other countries involved in the war.

Folic Acid

The therapeutics of folic acid has been especially interesting because, as Spies[1] put it, "it offered the prospect of a specific form of therapy with a pure chemical compound of known molecular structure." At first it seemed that a wide field of disorders of the blood and alimentary tract would be open to folic-acid therapy and that much new information would be obtained on the nature and mode of action of the anti-anæmic, or erythrocyte-maturing, factor. But experience has already contracted the therapeutic field, and the relation of folic acid to erythrocyte maturation has not yet been clarified.

In pernicious anæmia the short-term results of folic-acid treatment are uniformly good. The drug can be given by mouth in a dosage of 20 mg. daily or as a single injection of 50–100 mg. intravenously or intramuscularly. There follows a typical and early reticulocyte response, transformation of the marrow picture from megaloblastic to normoblastic, sustained rise of red cells and hæmoglobin, and striking clinical improvement. The response parallels, but is no better than, that obtained with a first-rate liver extract[1 2]: Frommeyer and Spies[3] thought that the balance was in favour of the liver. The long-term results, however, have produced unexpected and serious difficulties. The first concerns the involvement of the posterolateral tracts of the spinal cord. It was early noticed that folic-acid treatment did not improve the nervous symptoms—in fact, that some patients became worse even though the blood levels were satisfactory.[4] Next it was reported that patients apparently adequately controlled by folic acid developed signs of posterolateral cord sclerosis which rapidly became intensified. Wilkinson[2] had 6 out of 19 patients with signs of spinal-cord disease, and in 3 the signs appeared de novo within between transfusions (doses of antigen) given. Professor Diamond mentioned a group of 142 Rh-negative men, 43% of whom had demonstrable antibodies; 10% of these had had recorded reactions while another 33% had had symptoms and signs of reactions (not recorded as such) at the second, third, or subsequent transfusion. By contrast, immunity which has developed more slowly, as during a Rh-positive pregnancy in a Rh-negative mother, is stronger and more lasting and the subject is more liable to reactions after transfusions of Rh-positive blood, even the first. It is unwise to use a husband as a donor for his wife if his Rh grouping is unknown—he might be Rh-positive and so sensitise or induce a fatal reaction in his spouse. The importance of ante-partum, postpartum, or subsequent transfusions for Rh-negative women being of blood compatible in ABO group and Rh-negative cannot be too strongly emphasised. All women should be grouped (ABO and Rh) when first pregnant, and in affected and special cases the simple and specific Rh (genotype) of the father and children should also be determined.

[3] Frommeyer, W. B., Spies, T. D. *Amer. J. med. Sci.* 1947, 213, 135.
[4] Spies, T. D., Stone, R. E. *Lancet*, Feb. 1, p. 174.

Infants who show gross hydrops at birth, or during their first few days of life develop jaundice and anæmia with erythroblastæmia, enlarged liver, and spleen, or with kernicterus and later muscle incoördination and mental defect, are Rh-positive children of Rh-negative mothers and Rh-positive fathers. When the mother is Rh-negative and the father is Rh-positive and homozygous (Rh-Rh) every fœtus will be Rh-positive and will develop hæmolytic disease *in some form.* The chance of the fœtus being affected will be reduced to 50% if the father is Rh-positive but heterozygous (Rh-rh)—thus, in heterozygous twin pregnancy the healthy child is Rh-negative and the Rh-positive child is stillborn with hydrops or jaundiced. Since the first child of such unions, which constitute 13% of all marriages, is usually unaffected; the general chance of a Rh-negative mother having an affected child is 1 in 22 and the over-all incidence of hæmolytic disease is 1 in 200 births.

Until 1941 tests applied were unsatisfactory even in proved cases of erythroblastosis fœtalis. In 1944 Wiener and Race and Diamond were concerned with the demonstration of "blocking" or incomplete- or hyperimmune-antibodies. With hyperimmune antisera Rh-testing is as simply done as tests for the ABO groups, and Professor Diamond emphasised that there is now little excuse for the Rh, Hr, and Rh-Hr groups not being determined as a routine. By using six different sera the genotype can be determined with fair accuracy. Hyperimmune sera are prepared chiefly from Rh-negative male volunteers by giving them at short intervals over a period of several months 50 c.cm. transfusions followed by 0·1 c.cm. injections of Rh-positive blood. By ordinary agglutination methods, using red cells suspended in saline, the titre in these sera continues to rise for a time and then falls sharply. The fall is explained by the presence of "blocking" antibodies which are said to be adsorbed to and to protect the red cells from agglutination in the test. When however the tests are repeated with the red cells suspended in plasma or albumin instead of saline, the high level of the hyperimmune or "blocking" antibody content is apparent and titres of 2000 or 4000 are recorded. Ordinary agglutinins are demonstrable during the concerned pregnancies but are absent between and after them, while "blocking" antibodies may be demonstrated as long as 35 years later in a Rh-negative woman who has had a succession of children with hæmolytic disease. There is only the roughest correlation between the two titre levels and the birth of children with hæmolytic disease.

Jaundice and anæmia in the newborn remains a clinical problem, though the mortality has been reduced by treatment based on the work of the last five years. Twenty years ago, when treatment was by intramuscular injection of the father's blood, 40% of cases succum to jaundice, œdema, or cardiac failure and 15% of survivors showed evidence of brain damage. Betw 1941 and 1944 treatment was directed towards rep the destroyed red cells with Rh-negative blood in s transfusions and the case-mortality was reduced to 30 (Diamond). The fact that jaundice and anæmia appeare in such infants three to four days after birth suggeste that earlier delivery (37th to 38th week, at the discretio of the obstetrician) might reduce the duration of actio of the maternal (hæmolytic) antibody. Over a period two years, in a series of 350 cases, Professor Diamon reduced the case-mortality to 20% by combining ear delivery with small transfusions of Rh-negative bloo More recently it was shown that the cord blood ofte has appreciable amounts of circulating Rh-antibod (carried over from the mother) and this suggeste treatment by exsanguination-transfusion with R negative blood as soon after birth as possible. Th technical difficulties of the method—clotting in cannul &c.—are considerable, said Professor Diamond, and sinc heparinisation is contra-indicated because of the tendenc of these children to bleed (hypoprothrombinæmia) h and his colleagues use a special plastic catheter passe into the umbilical vein to reach the ductus venosus inferior vena cava. The infant's blood is graduall replaced with Rh-negative blood, 20 c.cm. at a tim through a two-way syringe set-up, until after an hou 500 c.cm. of blood has been transfused and 400 c.c *of the infant's blood replaced.* The umbilical vei has been used up to 18 hours after delivery; thereafte arm or leg veins are cut down upon and the plasti catheter is passed into the subclavian or femoral ve By this treatment the case-mortality has been reduce to 10%.

Much work has yet to be done before all the tissu changes and immunity mechanisms involved in thi group of diseases are fully understood.

CONSENT TO DEATH

THE Voluntary Euthanasia Society are planning t reintroduce into the House of Lords their Bill to legalis euthanasia for people suffering great pain from incurabl disease. The Bill, it will be remembered, was before th House in 1936 but was not given a second reading. At th annual meeting of the society, on May 21, Dr. E. A Barton spoke of the risk taken by doctors who acced to a patient's appeal for release, and argued that responsibility of this kind should not rest on the shoulder of the doctor alone. In a contribution to the sprin issue of *University College Hospital Magazine*, he mad the same point at greater length. Though cases needin euthanasia are rare—he has seen only half a dozen i fifty years—they are peremptory: the impulse to hel the patient at his own urgent plea is almost impossibl to deny. Many, he hopes, are willing "to risk criticis and worse by doing for a patient that which they woul desire for themselves under similar circumstances."

The present situation is sometimes cruel to the patient yet it is very doubtful whether legislation could mak things any better. The difficulties were discussed b Dr. Harry Roberts[1] when the bill was last before th House. Were he himself dying of carcinoma of th throat, he said, his hope would be that his doctor "with-out significant word or gesture" would "hasten the pac over a bit of bad going." He went on:

> "My exit would not be quite such a happy one if, as suggested in the Voluntary Euthanasia Bill . . . I had first had to make an application stating to the appropriate authorities that I had been informed by two medical practitioners, whose certificates I enclosed, that I was suffering from an incurable disease and that my nearest relatives

s in sprue and nutritional macrocytic anæmia. he conjugates are difficult to prepare and they are nly apparently pure; SUAREZ et al. point out that hey may be contaminated with naturally occurring onjugase-inhibitors. Folic acid, in the free form, s known to be a product of bacterial synthesis in he intestine of animals, and there is evidence that roduction also occurs in man,[17] so that accurate stimates of deficiency cannot be made. The number f patients so far treated with conjugates is small, nd the results are not always clear. For all these easons, the American school, while agreeing that liver extracts are concerned with the release of stored complexes of folic acid, suggest that liver extracts have a "more deep-seated action."[12] They point to the partial effect of folic acid and to the difficulty of explaining why such relatively large amounts of folic acid, compared with very potent liver extracts, are needed to produce a satisfactory response SPIES maintains that folic acid is an enzyme or coenzyme concerned with the formation of the anti-anæmic principle and that the principle is not folic acid but "a more powerful substance, which, when obtained in pure form, will be more efficacious per unit weight than any now available." There is clearly not yet enough firm information for the rôle of folic acid to be accurately assessed, and experience teaches us that resolution of the contradictions may take some time.

Annotations

NURSING IN PERSPECTIVE

HAVING assumed responsibility for a National Health Service from next April, the Minister of Health has assumed responsibility for finding and keeping enough nurses to make it work. The shortage of nurses, even more than the shortage of food, is world-wide, and it is partly the result of greater demands which modern medicine everywhere makes on nursing time and skill. Obviously, however, it is not going to be relieved without positive action in various directions, and important new proposals are expected in the forthcoming report of the Ministry's working party which is reviewing possibilities.

At such a time it is well that the situation should be seen in its historical perspective. An article published in last Monday's *Times*, and another in our Reconstruction column this week, take us back to the controversy preceding State registration as established by law in 1919, and display the difficulties arising from insistence on a single qualifying State examination. Florence Nightingale herself opposed this constricted portal of entry to the profession, and our correspondent argues that the time has come for a change of policy, by which henceforth the training schools should hold their own entrance examinations, arrange their own curricula, and grant their own certificates of proficiency. Schools recognised as reaching a suitable standard would receive State support in the same way as universities receive money from the State through the University Grants Committee, and their certificates would entitle the holder to State registration. Under this less rigid system these schools would have more freedom to make the best use of their material, both human and educational.

The syllabuses imposed by the General Nursing Council, and the significance attached to success in examinations, have done much to promote knowledge, but they have also lost the profession a great many girls who would have made excellent nurses. All will agree that the standards of teaching are ultimately more important than the standards of examination; and, whatever may be thought of the present proposals, the time has certainly come for some change of emphasis as well as for grants to the training schools apart from the hospitals they serve.

THE ROYAL SOCIETY ENTERTAINS

A CONVERSAZIONE is intended to promote conversation, and on May 29 the Royal Society gathered a notable assembly for this purpose at its rooms in Burlington House. Between conversations the guests looked at exhibits and demonstrations illustrating the range of scientific research. They witnessed attacks on plants by living flea-beetles transmitting a newly crystallised virus whose molecular arrangement has been indicated by electron microscopy; they studied diagrams showing how a stomiatoid fish is able to open its mouth widely; they examined mirrors and lenses (from the plastics division of Imperial Chemical Industries) made by a "surface-finishing" process which allows optical components to be manufactured rapidly, and hence cheaply, once the glass moulds have been prepared; they were initiated into the problem of the "correlated response," by which selection for one genetic character is liable to affect the expression of other quite different characters; and they enjoyed a colour film of growing crystals. Most nearly allied to medicine, perhaps, were a beautiful collection of microscopes from the Wellcome Historical Medical Museum; an exhibit of differential staining (in bone-marrow) of pro-erythroblasts and premyelocytes, depending on their difference in desoxyribose-nucleic acid charge; a meter devised by K. Mendelssohn for measuring radiation flux (energy/area/time) in order to prevent accidents to patients treated with radiant heat; and D. Herbert's demonstrations with the enzyme catalase isolated from *Micrococcus lysodeikticus*—the first bacterial enzyme to be obtained in a pure state, and also the first to make a whistling noise at Burlington House by its semi-explosive action on hydrogen peroxide. In entertainment appeal this whistle was beaten only by a mechanical model illustrating the uranium chain reaction, in which a single anarchical impulse caused a large number of groups of ping-pong balls, each representing a neutron, to be successively disrupted.

RHESUS FACTOR IN RETROSPECT

THOSE not numbered among the devotees of the rhesus factor may think that the group of conditions covered by the term "hæmolytic anæmia of the newborn" are a fairly recent discovery, but Prof. Louis K. Diamond, of Harvard, speaking at a meeting of the Royal Society of Medicine on May 23, recalled that the published work dates from 1900. In the early period (1900–10) the papers written on fœtal hydrops, familial icterus gravis, and erythroblastæmia were mainly English; in the second period (1910–20) the pathological findings were described by German workers. Since the rhesus agglutinins were recognised in human blood in 1940, extensive studies of erythroblastosis fœtalis from the clinical aspect have been supported by full serological investigations.

In the white races 85–87% of the population (negroes 95% and Chinese 99%) are Rh-positive. The Rh-negative remainder may become sensitised (immunised) to the Rh factor by being transfused with Rh-positive blood or by bearing a Rh-positive child, and may then have serious and even fatal reactions on subsequently being transfused with Rh-positive blood. Immunisation of Rh-negative persons following transfusion(s) of Rh-positive blood is not uncommon, but the level of antibody developed is usually low and depends on individual variations and on the number of and intervals

Modern Care of Old People

II

LIVING IN A SMALL GROUP

Hill Homes, Highgate

THE needs of the old vary with the state of their health ; and though the line between health and sickness is easily crossed in the later years there is no reason why an old person who feels well should be obliged to live the life of an invalid, or a sick old person be forced to do more than he is fit for. The hospital is not the right place for the one nor the residential home for the other, though transference from hospital to home and back again should be made easy. Fit old people are probably happiest in small homes with a family atmosphere. Both the Ministry of Health [1] and the Department of Health for Scotland [2] have lately endorsed this principle, urging local authorities to establish small homes for 30–35 old people in suitably adapted houses. Both encourage a greater degree of freedom in the homes than has been customary in the past—freedom for the old people to come and go at will, to keep personal belongings in a private place, to wear their own clothes, and to be visited on any day of the week. They also favour the use of light colours for decoration, and suggest that small tables should be substituted for the long dining table. Chairs should be comfortable, floors not slippery ; big rooms may well be divided into small rooms, and pictures should be used for decoration.

These principles in the care of the old have been established largely by the work of voluntary societies; and a particularly successful experiment along such lines is being conducted by the public-utility society known as Hill Homes Limited, of 16, Bishopswood Road, Highgate, under the chairmanship of Alderman Margaret Hill (Mrs. A. V. Hill).

One of their homes—the Delia Grotten Home, named after the first resident—was set up in 1938. The others have developed out of the experience gained in the Highgate Homes for Aged War Victims which were run on behalf of the Ministry of Health with the help of the Hornsey borough council. Some 130 old people are at present housed in the various types of home. The society was formed to maintain the happy plan of grouping in small communities both very old and also disabled old people. These latter are not received in the first instance if bedridden, but are not necessarily sent away if they become so in course of time. The homes are experimental, and endeavour to work out the most satisfactory methods of dealing with a difficult problem.

The committee found that, while the well-to-do and the very poor are catered for, those with small means, though often in great need of help, have no provision made for them ; and it was on these old people that they decided to concentrate. Growth of the scheme has been handicapped by scarcity of suitable houses and of labour to convert them ; but there are now four Hill Homes running, and a fifth about to open.

FOR THOSE WHO NEED NURSING

Since the aim is partly to experiment, the homes are run on slightly different plans. In every case the matron is a trained nurse, and one of the homes is in fact a nursing-home into which disabled or infirm old people can be moved when they become unfit for ordinary life. Here they are medically supervised, and nursed in bed if need be. If they need special investigation or treatment they are transferred to hospital for a time ; one of them spoke warmly of her happy return "home" after such an excursion. The bedrooms in this house are really small three or four bedded wards, very comfortable, with walls painted in light shades, and pleasantly c curtains to the cubicles. The old people busy them with needlework, or chatter sociably with their group, to whom they become much attached.

FAMILY LIFE

There are two sunny sitting-rooms and much made of a terraced garden in the summer-time. family atmosphere has been maintained : the home not suggest a hospital.

This principle of the family group holds in the o homes. One plan has been to fit a congenial little com together in a big comfortable room with an open (guarded) fire, comfortable chairs, convenient tables, the beds and dressing-tables of the party. Every resid sets out what possessions she likes on her dressing-t There are no rules, except that anyone who cannot in to the life of the home is asked to leave. The commi have set their faces against the principle of "safety fir Except in the nursing-home, the old people come go as they please ; if they lose their way there are alw policemen to help them, and aphasic ones can c their address in their pockets. If they want to risk g out in wet or snowy weather they are not preven The committee take the view that life, in order to worth living, must be lived ; and unnecessary restrictio designed to protect them, are as misplaced with the o as with anybody else.

The houses have central heating, so the old peo are not exposed to changes of temperature when t move about the landings or visit the rooms of friends. In a home shared by both sexes, the dining-room, equipped with small tables, has an open fire as well as radiators ; here all the residents meet for meals. There are always more women than men, for women live longer ; but the mixed society is welcome to both, and in the case of one couple friendship ended in marriage. In one home five or six rooms are occupied by women, two or three by men, and one by a married couple. All the homes have a few single rooms. Many of the residents have only their old-age pension ; these pay 28s. a week and

In the garden.

had been notified; my request being duly attested by a magistrate; if, further, my application had then to be submitted to an official 'euthanasia referee,' after whose approval seven days must elapse to allow time for appeal by a relative to a court of summary jurisdiction, which may then cancel the permit. Only practitioners who had been named for the purpose would be eligible to act as euthanisers, and the administration must take place in the presence of an official witness. I can almost hear the cheerful announcement: 'Please, ma'am, the euthaniser's come.'".

Dr. Barton, however, pictures no such cruel postponement of relief. He thinks England should be divided into areas, in each of which two doctors of high standing and ability would be registered, who would be called in by the general practitioner to carry out the final act. The patient would have to ask relief, and only urgent pleas would be taken into account. The consent of friends would not be asked, for if it was refused the patient must continue to suffer, whereas if it was given "misunderstandings might arise later." The two specialists would see the patient together, without anyone else in the room; after which the patient's own doctor would be heard, and a clear decision made; and after that the patient would be released. This again would mean moments of suspense and heavy responsibility for the patient.

THEIR FIRST CENTURY

At their convention, which opens on June 9 in Atlantic City, the American Medical Association will celebrate the 100th anniversary of their foundation; and in his history, which has been appearing as a pious serial in the *J.A.M.A.* since last November, Dr. Morris Fishbein aptly writes: "the birth of the Association followed travail of many months; the pains, the jealousies and the love associated with its conception forecast the great career to be achieved by this extraordinary progeny." Their first meeting was held at Philadelphia in 1847—the year in which Simpson first used chloroform in obstetrics, Semmelweis discovered the cause of puerperal fever, and Ludwig invented the kymograph. This year at the invitation of the association Prof. G. W. Pickering will give an address on Hypertensive Encephalopathy, Prof. H. J. Seddon on Nerve-grafting in the Limbs, and Sir Howard Florey, F.R.S., on New Antibiotic Agents. Other English guests will include Sir Heneage Ogilvie, Dr. R. M. B. MacKenna, Prof. John McMichael, Mr. G. E. Martin, Sir Stewart Duke-Elder, Dr. E. Ashworth Underwood, and Dr. A. R. Hunter. A commemorative 3-cent maroon postage-stamp is to be issued by the United States government, and the design chosen is Sir Luke Fildes's picture *The Doctor*.

INTESTINAL ANTHELMINTICS

A recent recommendation[1] in France to place oil of chenopodium and its active principle ascaridole in table C of their poisons list directs attention to the possible dangers of anthelmintics or vermifuges. Ascaridole has undoubtedly been responsible for occasional fatalities, but it is well to recall that none of the intestinal anthelmintics is free from such a risk. In the mass treatment of tropical populations for worm infestation deaths have resulted from the use of almost every known anthelmintic.

In normal clinical practice the chance of accidents in the treatment of intestinal parasites can be minimised by following a few principles. Individual idiosyncrasy to any of the usual anthelmintics is almost impossible to forecast, but happily rare. Some protection against it can be obtained by giving the full dose of the drug in three parts at half-hour intervals, rather than as a single draught, if the first dose produces ill effects the others can be abandoned. Dividing the dosage is also to be commended because it prolongs the contact of the drug with the worms and thus increases its action. Most intestinal anthelmintics are soluble in alcohols and in absorbable oils and fats. These solvents must therefore be avoided over the period of treatment, to lessen the risk of the drugs being absorbed from the gut. Again, once the drug has done its work it should be removed from the body as completely and as rapidly as possible, further to lessen the risk of absorption. To this end a vigorous *saline* purge should be given one or two hours after the last dose of the drug, to sweep it from the bowel. This vigorous purgation serves the added purpose of removing worms temporarily incapacitated by the drug, which if left in the bowel would recover and re-establish themselves there. If these simple precautions are taken anthelmintic treatment can be embarked on in otherwise healthy patients without anxiety and with a good hope of success.

SMALLPOX IN NEW YORK

Smallpox is a rare cause of death these days in the United States. In the last fifteen years fatal cases have never exceeded 50 annually, though Seattle had 68 cases, with 20 deaths, last year. It is thirty-five years since anyone died of the disease in Manhattan, but this record has now been broken by the death of a Mexican businessman who had travelled from Mexico City to New York a week before by bus, a four days' journey. The Mexican felt ill on arrival. His wife took care of him at their hotel for a time but finally sent him to hospital, where he died. His symptoms were atypical, and nobody knew he had had smallpox until two people at the hospital developed a typical eruption. Immediately the public-health services were mobilised. The city of New York set out to vaccinate its 7,500,000 inhabitants in three weeks. Air transport solved the problem of getting enough vaccine, and the programme went ahead at the rate of 250,000 a day. Dispensaries, hospitals, police stations, factories and offices, labour union halls, and doctors' surgeries were transformed into clinics, and the newspapers and radio stations distributed official announcements and advice to the public. Meanwhile the route of the bus was traced and precautions were set on foot along the way. In Camden, New Jersey, there was a death from smallpox, and mass vaccination began immediately there and in Philadelphia nearby. Jersey City, across the Hudson from New York, immunised 50,000 inhabitants, and the State of New Jersey authorised the expenditure of $65,000 to immunise 180,000 people. The Americans have not forgotten the tragic example of Manila, in the Philippines, where vaccination had become lax and a sudden epidemic in 1914 caused 50,000 deaths. In England mass vaccination during an outbreak is not ordinarily adopted. As Dr. W. H. Bradley told the Royal Sanitary Institute on May 14, last year 15 introductions of the disease from outside led to only 40 secondary cases, thanks to the prompt application of routine measures of control.

THE NEW REGIONAL POSTS

Names of members of the 14 regional hospital boards appointed by the Minister of Health under the National *Health Service Act* will probably be announced in the near future. Each board will require an administrative medical officer, and doubtless one of its first acts will be to advertise this important post. The salary offered is likely to range from £2000 a year in the two smallest regions to £2500 in the largest ones, and the appointments made will be of interest not only to the successful candidates but also to the whole profession.

We regret to announce the death on June 1 of Dr. Noah Morris, regius professor of materia medica and therapeutics in the University of Glasgow; and on June 3 of Dr. Richard Clitherow, M.P.

ment grants them an appropriate allowance. The residents are responsible people, and have not presented any problems by rash spending. Many of them are women living alone in cottages or in single-room flats, but there are some married couples, and often two friends will share a cottage. Each flat consists of a good-size bed-sitting-room with a gas-fire, and with a kitchenette opening from it; and the residents in this block share bathrooms. Some of the older cottages are without bathrooms, but baths—and plenty of hot water—are always to be had at the *nursing-cottage*.

At the nursing-cottage there is one moderately large ward, with cubicles, for women, a smaller ward for men, and an isolation ward for a single case; 11 patients can be received at a time, and since the nursing staff are able to visit and nurse convalescent patients in their cottages, this small number of beds proves adequate. A doctor visits the nursing-cottage three times a week, and besides treating the inpatients sees any other residents who come for examination. Surgical cases are transferred to one of the neighbouring general hospitals. The nursing staff consists at present of the matron, a trained sister, and three assistant nurses, two of whom have had mental-hospital training; and a second trained nurse is to be added to the staff. Residents pay nothing for medical and nursing attention, but if they move into the nursing-cottage for treatment they pay 15s. a week for their board: there are no other charges.

Much supervision naturally falls to the matron, who has quarters in the central building and is on friendly terms with the residents. Housework in the cottages is done by the residents themselves; and plans are on foot to establish a home-help service. Old people who cannot look after themselves—mostly widowers, or old people with infirmities—live in the rest-home, and are given complete service. Their rooms, each with its own gas-fire, are furnished for them as bed-sitting-rooms, and cleaned by the staff; their meals are prepared for them and served in a common dining-room; a warm common lounge, with wireless and plenty of easy chairs, has some of the quality of a club.

Apart from life in the rest-home, there is little communal life in the estate. There is a good hall in the central building, suitable for concerts and whist drives, but this has not been used since before the war. Plans are now being made to use it again, but for the most part residents prefer to follow their own interests, joining in the church or social activities of the neighbourhood and visiting chosen friends in or outside the homes. Though the Linen and Woollen Drapers are entirely responsible for developing and supporting the cottages, the residents are never made to feel that they are recipients of charity, and certainly never entertain such a notion themselves. They have worked for the textile industries in the past, and now feel they are receiving their due. Mr. Donald Cave, the secretary of the institution, suggests that the example of the Linen and Woollen Drapers should be followed by other industries: if each took care of its own, much distress among old people could be prevented.

Worthing Council of Social Service Homes

Two similar voluntary homes are sponsored by the Worthing Council of Social Service. One of them—the Church Walk Home—is for old people who have nothing but the 33s. a week they derive from the old-age pension and their public assistance allowances. As in the Hill Homes, they pay 28s. a week and keep 5s. to spend, and these contributions are sufficient to keep the home running. The comfortable house in a quiet sunny street was left to the council, and the gracious solid furniture was also a bequest. Here two or three old people share each bedroom, but instead of living in their rooms, as the residents in the Hill Homes do, they share a warm and comfortable common-room, well stocked with easy chairs. The sunny french win opens on a small paved terrace where there is a g seat, with a pleasant garden beyond. The home small, taking only 14 residents, and the dining- with its two shining family tables will seat them comfortably. Electric stoves set high on the walls their bedrooms are directed downwards to warm air; they are turned on by the matron from a mas switch for half an hour or so before the old peo go to bed, and before they get up in the morn *Mrs. Bernard Methold, the secretary of the council,* w has had much to do with the work of founding the hom finds that if they keep the old people warm they ke them well. Every room has its own washbasin, wi running water; and though there is not room fo separate wardrobes and chests for everybody, each re dent has her own share of hanging-space and drawe and space to put out the photographs and ornamen she likes.

The residents are carefully chosen, and taken for while on probation before they are finally accepte If they fall ill they are visited by one of two honorar medical officers, and if necessary sent into hospita Colds and trifling illnesses are nursed by the matron who is on the State register. Her work is catholic, for besides looking after the welfare of her old people she cooks their meals, and manages the house with the help of daily cleaners. Some of the old people in this house have foot troubles, for which an honorary chiropodist attends them. They help with the sewing and mending, make their beds and dust their rooms, and, if they wish, give a hand with table-laying, washing-up, or other light jobs.

The second home, the Caer Gwent Club, which had only been open about a month when visited, is much larger, being capable of taking 24 residents. At present there *are 18, and the number will not be increased* until a fire-escape to the top floor has been completed. The club is designed for people with an income of two to three pounds a week, and every resident pays £2 2s. weekly. This comprehensive fee covers all essential needs. Each resident has a room to herself in which she may, if she wishes, place her own furniture. Every room has a radiator, and some at present have gas-fires, but these are to be replaced by electric convection stoves which can be plugged in wherever they are needed. Since they have no exposed wiring and are too solid to be knocked over, these stoves are specially appropriate for use in a home where old people have rooms to themselves, though of course they are not as cheerful to look at as the open fires of the Hill Homes. The club has two comfortable common-rooms where the residents can meet and talk, play cards, or listen to the wireless. So far there is only one man among them, but it is hoped that others will join him when the remaining rooms are opened. The big dining-room has small tables; but its Edwardian stained glass windows unfortunately give it rather a sombre air. The garden of this house is particularly pleasant and well kept, with wide sunny lawns, and plenty of flowers and trees. The matron—again a State-registered nurse—has non-resident domestic staff to help her, and is shortly to have a resident cook. She was formerly the matron of the first home, so she brings good experience to this new venture. *The residents have hardly settled down to their new life yet, but they* expressed pleasure in the comfort of the home.

Messrs. Sharp and Dohme Ltd., of Hoddesdon, Herts, have issued a revised version of their coloured chart "Characteristics of Certain Sulphonamides." The chart measures 17 in. × 11 in. and summarises the main pharmacological and therapeutic data of six widely used drugs in a convenient form for reference. It will be sent free of charge to any doctor applying.

ain 5s. for pocket money. All the residents y something, up to a maximum of £3 3s. a ek; and all the houses reckon to be self-pporting, though this is becoming difficult r those charging less than 35s. weekly.

One house is a residential club for educated men, some of whom furnish their own rooms. ey arrange their own pursuits, which clude bridge and music, though only three them are under 80. The new home which is ortly to be opened is to be for men and arried couples, and will also have some bicles in which old people can stay for a ne while their relatives are on holiday, or hich they can use after coming out of spital, until they are fit to go back to dinary life.

These homes seem a first-class example the care of old people. The small home 25–40 residents has a happier, more timate atmosphere than can be achieved a large institution. Throughout the country just now ere are old people living dangerously lonely and glected lives, as well as young people handicapped in eir own development by the need to give close care to single old relative. In both cases the old people could e more happily and fully in the company of a group their contemporaries, while the strength of the young people could be used less extravagantly for the service of the community. Local authorities should be quick to adopt the principle of the small home, which though not new is not used nearly widely enough.

A little mending.

THE LOCAL AUTHORITY'S PART

One difficulty encountered by the Hill Homes is worth emphasising, for unless it can be removed it may imperil the whole scheme. If the pleasant family atmosphere of the homes is to be maintained it is essential that there should be some other haven for old people who become unsuitable for this type of care. Patients with delusions, sometimes of persecution, and those with senile dementia, for example, cannot be fitted into the plan; and it is inevitable that a proportion of residents will eventually become mentally incapacitated in these or other ways. The help of the local authority is badly needed in finding other quarters for old people in such straits; for if they are not withdrawn the character of the homes will gradually change, and instead of offering congenial surroundings for sane and active old people they will become, like the old poor-law institutions, a limbo for those beyond all hope and understanding. The county in which the Hill Homes are situated in many respects takes the lead in public health; but it so happens that its arrangements for the care of the old—owing to lack of buildings and staff—are defective; and so far the authorities have not been successful in finding sufficient quarters for old people who deteriorate. If schemes of this kind are to develop as they should, local authorities must not only sponsor such homes themselves but encourage voluntary bodies to found them; and this can hardly be achieved unless the authorities will undertake the care of residents who become unsuitable. Under the National Health Service, the care of the sick and the able-bodied old people will be respectively in the hands of the regional hospital board and the local authority. Two-way traffic in and out of hospital, and transfer from one authority to the other, must be made as easy as possible.

A party in one of the rooms, all aged 90–100.

The Linen and Woollen Drapers

Care on an unusually generous scale is offered to elderly members of the textile trades, or their old dependents, by the Linen and Woollen Drapers' Institution and Cottage Homes. These houses, built on an open site at Mill Hill, include 129 cottages, a block of 20 flats, a rest home, and a nursing-cottage. Residents, elected by the board of management, must be over 60, must bring a medical certificate of good health on admission, and must be sponsored by some person well known in the textile industries. Though the cottages have increased in number since the estate was first planned in 1898, they have not kept up with the demand; there is a waiting-list of some 90 people, many of whom have waited several years.

The cottages are solidly built on lines in favour at the beginning of the century, and contain two or three rooms and a kitchenette. The rooms are sizable, with cream walls and sash windows. The only institutional touch is to be found in the dark brown paint used for most of the woodwork; but in these days, when a sum of only £10 may be spent on repairs and redecoration of any one of the cottages, it is hardly possible to change this serviceable if depressing colour. All the sitting-rooms have gas fires, and the kitchens are equipped with gas-cookers; 'Ascot' gas water-heaters are now being put in.

Tenants of the cottages and flats pay no rent or rates; they move in with their own furniture, and live the same sort of life that they would do in any private house—catering for themselves, looking after their own garden borders, having visitors, and going away to stay with friends. If their income is too small for them to meet their bills for food, fuel, and light, the board of manage-nurses. Thirdly, concentration of attention upon the attainment of State registration induces in the nursing hierarchy an attitude of having little or no use for those who cannot make the grade; and this may underlie much of the tension between the trained staff and the student nurses. We cannot rule out the possibility that nursing has suffered, as Miss Nightingale predicted, from a tendency to exalt examinations at the expense of the fundamental things. Are we still getting the same proportion of able women of the right kind to take up nursing in their late twenties and early thirties—the women who can bring to nursing so much that it needs? And if not, has not the emphasis upon examinations a good deal to do with it?

These considerations, taken together with the gravity of the staffing problem of today, are sufficient to call in question the whole policy pursued since 1919.

AN ALTERNATIVE

An entirely different approach was surely possible—the encouragement by the State of the training schools by means of a system of grants in aid. This was the approach *adopted by the State (also in 1919) in its* attitude to the universities. By means of grants from the Exchequer, coupled with a system of visitation to ascertain their needs, the State has enabled the universities and the various colleges greatly to increase the number of graduates, while at the same time leaving them to select students for themselves, and to determine the standard required for the award of a degree.

Let us suppose for a moment that in 1919 central action in nursing had followed this analogy, and that instead of an examining body there had been set up a mechanism similar to that of the University Grants Committee, with substantial funds at its disposal to help all recognised training schools for nurses. Would it not have been immediately apparent that one of the most pressing needs was financial support for the training school, which would set it free from dependence upon the hard-pressed hospital budget? Miss Nightingale, it may be remembered, set great store by the financial independence of her school at St. Thomas's, and the obvious advantages of such a plan—adequacy of staff for teaching, and adequacy of accommodation—need no emphasis. A system of grants would have given such a central body a real control over standards, without the disadvantages which are attached to the present system of State examination; and it would have been a control of a positive rather than of a negative kind, progressive rather than static.

Faced with a sense that standards are slipping back rather than rising, the General Nursing Council of today turns to the imposition of test examinations for entrants, and the elimination of the smaller training schools—both steps which are likely further to embarrass the hospitals in their search for staff. In a similar situation a body such as we have envisaged, with funds at its disposal, would concentrate its attention upon the weaker schools, their needs and handicaps. Its first thought would be for the number and quality of their teaching staff, and it would not forget facilities for the training of the teachers. Has not nursing suffered from the failure to provide any adequate central funds for the training not only of sister tutors but of ward sisters, and all others whose work includes teaching? It may well be argued that the defect is traceable to the fact that recognition of nursing in 1919 took the form of the creation of a licensing body, rather than that of one possessing the financial and other powers necessary to transform a system of apprenticeship into a professional training.

RIGHT USE OF CENTRAL MACHINERY

The neglect in 1919 to provide the funds needed was a failure of imagination in regard to the real nature of the need. It is surely to this rather than to any other source that we must attribute the frustration in which we find ourselves.

What nursing needs today is relaxation of unifor There has been a divorce between training and sta The way to bring them together again is surely to the emphasis back on the individual hospital and training school, and to use the central machinery to and encourage, rather than to regulate and restrict.

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS

OPENING the 171st session of the council on June Sir HERBERT EASON, the president, spoke with d regret of the death of Mr. Douglas Bartley, legal ass since 1927, and announced that Mr. Reginald Vaug K.C., had agreed to act as legal assessor during the pre session. Of those leaving the council Lord Hac had served as Crown nominee for fifteen years, be succeeded by Mr. J. J. Robertson, M.P. for Berwick Haddington. The ever-increasing burden cast u him by developments in the relations between medic and the State had made it impossible for Sir W Jameson any longer to give his time to the busine of the council. "In his short but memorable term office," said the president, "Sir Wilson proved hi a worthy successor to the several distinguished ch medical officers who have preceded him here. He h left an indelible impression on the rules for Diplomas Public Health which, as chairman of the Public Healt Committee, he presented to the council in 1945; and . . . on the recommendations as to the Medical Curriculum which the council adopted in February. We shall al miss Sir Wilson's great experience in all matters affecting our profession, his wisdom, and his sound political sense." His place as a Crown nominee was being taken by Dr G. A. Clark, representative of the University of Sheffiel since 1938, in which capacity Dr. Clark was succeeded by Dr. J. G. McCrie, who will shortly take office as full time dean of the Sheffield faculty of medicine. The vacancy caused by the death of Sir Kaye Le Fleming had been filled by the election of Dr. J. A. Brown, o Birmingham, as a direct representative of the medica profession in England. As an additional member of th council under the Dentists Act, 1921, Mr. Adam Cubi was followed by Mr. Duncan MacGregor.

Speaking of the Recommendations as to the Medica Curriculum,[1] over 2000 copies of which have bee circulated to the licensing bodies and medical schools the president remarked that these would no doub receive attentive consideration.

> "But I should like once again, on behalf of the council to emphasise that the last thing which the council woul wish to do, even if they had the power, which they have not would be to impose on bodies and schools either a uniform curriculum or a uniform method of teaching the subject which the curricula in the several schools include. On the contrary, as is pointed out in the introduction to the recommendations, all that the council are attempting to do is to indicate to bodies and schools what should be the minimum content of any curriculum designed primarily for students who intend to enter general practice, while leaving bodies and schools, subject to the observance o that minimum, to interpret the recommendations in thei own way and in accordance with their individual views and experience."

In conclusion the president expressed the thanks of the council to those who, as chairmen of the committees concerned, bore the brunt of the arduous task of preparing the recommendations. These were Prof. R. J. Brocklehurst, chairman of the Committee on Pre-medical Studies, who was also called to the chair at the meetings of the Education and Examination Committees at which the conclusions of the Curriculum Committees were adjusted for submission to the council; Prof. H. R. Dean, chairman of the Committee on Pre-clinical Studies; Sir Leonard Parsons, chairman of the Committee on Clinical Studies; and Sir Wilson Jameson, chairman of the Committee on Social Medicine and Public Health.

Reconstruction

THE NURSING CRISIS

State Examinations and the Training School

FROM A CORRESPONDENT

THE nursing world today presents a strange scene. There is a great crisis, beyond all question; many of our publicly provided hospitals are so short of nursing staff that a large proportion of beds have had to be closed. Contrariwise the great voluntary hospitals still have waiting-lists, and the total number of nurses qualifying has risen appreciably since pre-war days, from 9000 to 13,000 per annum.

A strange medley of remedies are proposed. The reinstitution of an examination for entrants, and control of the assistant nurse, is advocated by the General Nursing Council. The Ministry of Labour intensifies its publicity campaign inviting the help of all and sundry, and there is talk of a two years' basic training for everyone alike. Still the crisis remains and the Ministry of Health faces the difficult task of obtaining the staff required for the expansion of the hospital services. We have somehow, it seems, lost our way.

IN HISTORICAL PERSPECTIVE

As every schoolgirl knows, hospital nursing was until the middle of the last century undertaken by untrained women; some, perhaps most of them, with a natural aptitude for the work, but including also many who brought discredit upon their calling. Then came the training schools of the Nightingale era, which eventually brought the leading hospitals so many probationers that these outnumbered the trained staff and undertook the greater part of the actual bedside nursing. Once trained they went out to spread the Nightingale gospel up and down the hospitals of the land.

These schools were essentially for the training of leaders and pioneers; they developed a high standard of selection appropriate to the object they had in view; and their trained nurses earned, wherever they went in hospitals and in the world at large, a reputation that gave to hospital nursing a distinctive character and a high social status in the community. This in turn played its part in attracting others. As the years passed, more and more hospitals set up training schools, until at last it became an accepted practice that a hospital with pretensions to being a general hospital of any size maintained its training school and looked to the body of student nurses to undertake the greater part of the bedside nursing. The process was carried still further with the upgrading of many of the hospitals belonging to the guardians and (since 1930) to the local authorities.

In practice, however, as the training schools multiplied, changes inevitably occurred. Looking back it is only necessary to trace the course of events to see that the very process of multiplication of training schools should have dictated a modification of the object and therefore of the standards of selection and attainment. The primary object of the average training school was no longer to train leaders but to train the rank and file. Two alternatives were then open: either the general standard could be modified to meet the needs of the far larger proportion of the community passing through the training schools, and special additional courses could be devised for the future leaders; or provision could be made for a wide range of selection and achievement within a loosely organised system. In fact, however, the matrons of the principal hospitals in the last generation with great unanimity set their faces against anything which might be regarded as lowering the standard of nursing in which they had themselves been trained. They thought, perhaps naturally, of their own hospitals and of the effect of any changes upon them, and they were not provided with any adequate data regarding the staffing needs of the more backward institutions.

Training and staffing, although bound inextricably together by the apprenticeship system upon which our hospitals were conducted, became divorced at the top, and the problem of staffing was left in the air. It fell back upon the individual hospitals. Where the matron could not find students of the standard required for State registration, she was free to do her best with untrained staff—the modern equivalents of the nurses of the old pre-Nightingale days—and girls below the age limits required by the training schools.

STATE REGISTRATION

The stamp of official approval had in 1919 been conferred on these tendencies by State registration, and the establishment of the General Nursing Council and its examinations. Is it possible that we are today paying the penalty for something that went wrong in 1919?

The younger generation today take State registration for granted, and many are scarcely aware that it was preceded by some thirty years of controversy. It had been advocated as a means of improving the status of the profession, and of protecting the public from incompetent persons calling themselves nurses. Miss Nightingale's vote had been against it, and the project had caused her deep anxiety. But she had died in 1910; and when State registration was carried in 1919, opposition had weakened. At a time when there was a surge of feeling in favour of votes for women and all that went with the vote, it was generally felt that registration would help to establish nursing as a profession comparable to medicine. The example set in this country was widely followed abroad.

What actually happened? It was never practical politics to provide that all nursing should after a specified date be undertaken only by State-registered nurses. Since many hospitals and nursing-homes had to continue to rely on untrained nurses for their rank and file, one of the major objects, that of protecting the public from the untrained nurse, was at once lost sight of; and State registration became almost an end in itself.

An attempt to retrieve the omissions of 1919 has led in the last year or two to the Act now on the statute-book to control the untrained nurse by providing for a roll of existing assistant nurses, together with provision for a two-year practical training in future. No-one is to be allowed to use the title "nurse" who is not either a State-registered nurse or an assistant nurse. The conception is reminiscent of that of 1919. If we could be sure that the two categories of trained nurses would together provide enough nursing staff for all our needs, there would seem to be no cause for anxiety. Such is, however, far from being the case. The new two-year training for the assistant nurse is an experiment, and no-one knows whether the effect of the two Acts taken together will not be to keep out of nursing many women of a kind who have hitherto lent a useful hand, and whose help can ill be spared now.

CASE AGAINST PRESENT SYSTEM

Nobody will wish to deny that much has been achieved since 1919 in raising standards in backward training schools, and it is unnecessary to expatiate on the more obvious advantages that have followed. On the other hand, the case against the present machinery of State registration is very strong. First it is confronting the less fortunate hospitals with an impossible dilemma; either they must go short of staff, and so further aggravate their shortage, or they must employ for nursing work women called by some other name than nurse. Secondly, the imposition of a uniform standard prevents the individual training school from adapting its requirements to the type of woman available to it, and is thus a primary factor in the high wastage-rate of potential

Letters to the Editor

DENTAL CARIES

SIR,—Reduction of activity below a physiological minimum leads to atrophy in bones, muscles, peripheral nerves, and any organ physiologically connected with mechanical functions. The teeth being part of the bony skeleton, it is reasonable to suppose that they, like bone react to such disuse with demineralisation and atrophy. For various reasons these changes cannot readily be demonstrated in teeth, by either radiography or chemical analysis; but the effects of disuse can be estimated from a world-wide survey of different races living under different dietetic and other conditions. In making this survey several factors possibly responsible for caries have to be considered.

Mineral Deficiencies.—Poor teeth are found in parts of New Zealand with a low calcium level in the water, in parts of England with a medium calcium level, and in parts of South Africa with a high calcium level. Good teeth were found among natives in Alaska regardless of low or high calcium or phosphorus intake. There appears to be no correlation between calcium and phosphorus intake and immunity from caries.[1] [2]

Fluorine Deficiency.—In South Africa, Kenya, and Australia dental decay is prevalent among the white people, while the non-assimilated natives of the same places are hardly affected, though using the same drinking-water. Tea has a high fluorine content but does not prevent caries in the English.

Poor Mouth Hygiene.—Filthy mouths are often free from caries, and no relation is in fact apparent between oral hygiene and caries.[3] [4] The incidence of toothbrushes is often in inverse proportion to that of sound teeth.

Inadequate Sunshine.—In regions with much sunshine the teeth may be comparatively good (southern U.S.A.) or very poor (South Africa, Kenya, Australia), and in regions with little sunshine the teeth may be good (Eskimos, Maoris in southern New Zealand) or poor (England).

Hereditary Factors.—The countries with the worst dental conditions are all inhabited by people of British stock, but a racial influence is disproved by the fact that natives in any part of the globe who fully adopt British food habits acquire dental caries to the same degree as the British. It appears that all human races are equally susceptible to dental caries.

Vitamin Deficiencies.—In New Zealand, which has the highest caries incidence in the world, butter, milk, and fresh fruit are abundant, and the population has very good health apart from its teeth. Investigations in the Kangra district of Northern India, where severe malnutrition, rickets, and osteomalacia are extremely prevalent, showed that almost perfect teeth were compatible with severe rickets.[5] In American prisoners-of-war released from Japanese prison camps after suffering from long-continued multiple vitamin deficiencies and severe malnutrition the number of carious teeth was less than that of the same age-group living under normal conditions.[6]

Overuse of Refined Carbohydrates, especially starch.—In central and southern Europe, where the teeth are comparatively good, the food is rich in refined carbohydrates. In New Zealand, with the worst teeth in the world, proportionally more proteins and less starch are consumed than in most other countries, the diet consisting mainly of meat, eggs, milk, and cheese. On the other hand, protein cannot be held responsible for dental caries, because the Eskimos, who live almost entirely on meat, have sound teeth.

Too Much Sugar.—In central Europe, where meals ordinarily conclude with a cooked sweet dish, teeth are fairly good. Negroes in the West Indies, who habitually chew sugar-cane, have excellent teeth. The sugar sumption per head is higher in North America than England, yet American teeth are much sounder.

Dental Disuse.—In New Zealand dental disease rampant among the British population and among Maoris who have adopted a British diet, but is among Maoris keeping to their traditional diet. already indicated, the British diet in New Zealand no obvious deficiency, but a striking characteristic the food as eaten is its softness. Almost all of it can swallowed without mastication: the meat is thinly c and taken in small pieces that may or may not be chewed the breadcrust is usually removed and thrown away and proper use of the teeth is considered bad tabl manners.

Food eaten with the aid of cutlery rarely requires re mastication, and in civilised society the number of sol foods eaten without cutlery is small. By far the mo prominent of them is bread, and it is interesting compare the dental conditions in various countries relation to the customary thickness of slices and th types of crust:

Country	*Thickness of slices*	*Crust*	*Teeth*[7]
Australasia ..	1/8 in.	Soft	Very poor
England ..	1/8–1/4 in.	Soft	Poor
United States ..	1/3–1/2 in.	Mostly soft	Fair
Central and Eastern Europe ..	1/2–3/4 in.	Tough	Good
Italy	1 1/2–2 in.	Tough	Very good

Prevention of Caries.—In osteoporosis or bone atroph there is "abnormal porousness of the bones by th enlargement of the Haversian canals and by the formatic of cavities; the atrophic changes, in many instance are caused solely by disuse."[8] I suggest that the path logical condition underlying dental caries is similar— disuse odontoporosis. If so, the importance of tough foo for the teeth lies in the prevention of decalcification fro disuse, and not in its detergent action, which is limite to a fraction of the tooth surface and affects least th places where food lodges and ferments. In primitiv peoples with a low caries incidence the teeth are ofte very dirty; the incidence of salivary calculus and dental plaques may be high[5] and the bacterial flora the mouth abundant. Frequent and careful cleansing the teeth does not appreciably diminish caries: th toothbrush is ubiquitous and victorious, but carie flourishes more than ever.

The accepted modern nutritionally sound diet, wit well-balanced minerals, vitamins, and calculated ingre dients, seems to have no bearing on immunity to carie This is in line with the well-known fact that an increase supply of minerals and vitamins cannot remineralise bone decalcified from disuse; it can be done only b active use of the limb. Similarly, the prevention of dent caries requires the addition to the diet of tough matte The addition of some hard breadcrust (old Swedish c Italian type bread) to the daily diet would suffice t maintain fairly good teeth with a reasonably low carie incidence. Carrots, celery, apples, and fruit generall are of little use in this regard; biscuits, cracking har food, and toast are still less suitable; while chewing-gur is too elastic and soft. Chewing of sugar-cane has bee found useful in the treatment of odontoporosis, but grea care must be taken at first, because some of the atrophi teeth may break. If rice is the staple food the preventio of caries demands the consumption of undercooked rice leaving the grinding of the grains to the teeth. Wher this is the custom, as in parts of the Philippines, the teet are excellent; whereas in parts of China, where the ric is well cooked, the teeth are poor.

After a lifetime of chewing the teeth may be groun down and shortened, as in old horses, but are free fron caries. In fact attrition and dental caries occur in invers relationship; they usually exclude each other, excep when the attrition reaches the pulp cavity and furthe chewing becomes painful.

Conclusion.—Reviewing the factors commonly blame for endemic dental decay—such as mineral deficiencies fluorine deficiency, poor dental hygiene, inadequat

In England Now

Running Commentary by Peripatetic Correspondents

HAVING at last visited Eire I can now reveal that is a country of wide straight roads, ass-carts, and hawled women ; of bare-footed and undernourished ildren ; of humble indigence and evasive answers ; mingled friendliness and suspicion ; of teetotal bar-aids ; of single-track railways ; of abundance of food d drink for those with the means to pay for them, and lack of most other material comforts ; of dogs and iests ; of ruins, squalor, and desuetude ; of great tural beauty ; of too much peace ; of brooding sadness d listlessness. Mirabile dictu, we saw no rain in Eire. ither did we see a blood-horse, a foxhound, or a game rd.

* * *

The man who travels by air today will enjoy the part his journey that he spends in the air. He will find odern transport planes fast, safe, and comfortable, e pilots skilled, the crews attentive, the food excellent. he is undertaking a one-stage journey he will be unlikely suffer inconvenience. But if he is on a longer journey ich touches several countries in transit he will find a ry different state of things. For every hour that he ends in comfort in the air he will spend forty minutes the ground subjected to every discomfort and indigty. He will rise three hours before the plane is due to ke the air, and he will normally spend three hours ter it touches down before he enters his hotel room. ven though the day's flight is only four or five hours he ust still wake before dawn and wait about in the night r.

Further, he is made to realise that the purchase of air ticket in itself transforms him from a harmless tizen into an international suspect. For every country which his plane may possibly call, even for half an our to refuel, he must obtain a visa and pay for it, and ust fill up a questionnaire saying why he wishes to visit at country and when he was there before, and must give details of his past life and evidence of multiple inoculaons. Whenever on his journey he comes down in a esh country, he must stand with his fellows in a queue, d trickle slowly, very slowly, past a group of officials. he more backward and therefore aggressively nationalist e country, the more irritating will be the inquisition, ven to the entering longhand into a ledger of every etail of every passport down to the colour of eyes and air, the inquiry into his day-to-day movements for e previous fortnight, and the examination by a health fficial. If he is due to stop the night he must in addition ass through the Customs and have his money counted nd entered on his passport. Finally he is driven ten to wenty miles to a hotel, where he is billeted with one or wo other fellow-travellers in one of the less good rooms nd treated with all the civility that a non-paying guest sually receives. After a few hours' sleep he is roused gain at 4 A.M., to face the same long drive and pass hrough the same currency control before he resumes nce more his seat in the plane.

At every major stop he must, in addition, face the ncertainty as to whether he will, in fact, continue on is journey at all. To the humble traveller the word 'PRIORITY" looms large. Anyone on an important ission, anyone with political pull—in some countries nyone who has distributed backsheesh in the right uarters—may displace him, and he may be stranded t some out-of-the-way island or junctional airport, hort of money, unsuitably dressed, to wait for that ndefinite opportunity when a plane shall come along ith room to take him farther on his journey.

When his route involves a change from one air line o another his troubles increase. Competing services ake a delight in disclaiming all responsibility for the ookings made by other companies on their planes, and he unfortunate traveller may find himself faced with the choice of abandoning hope and travelling for a week by land or sea to his destination twelve flying hours away, or seeing his name go to the bottom of a list lready filled up for a week or two ahead. Those who re skilful in the use of bluff, threats, entreaty, or palm-oil may get into the air ; the meek inherit the earth.

This is all very wrong. What should be the pleasantest form of travel is now the most harassing, for reasons which are none of them inherent in flying and which could all be removed. Here are a few suggestions from one who is recovering from a series of journeys.

1. Priorities should be abolished altogether. Governments, services, businesses, and wealthy individuals who require air transport at short notice should hire special planes for the purpose.

2. There should be a firm liaison between all air lines, so that a traveller can book from the start to the finish of a complex journey and be sure of a connexion at each stage, and an allotted seat in a specified plane. The scramble for seats that is often seen at night stops could be avoided by giving passengers a seat for the duration of their trip, and allotting seats before emplaning to those who join at intermediate stops.

3. The time-table on the ground should be drastically revised to cut out delays. At present an average of three hours elapses between the summons and the start, much of it spent waiting because officials have not yet arrived, standing in interminable queues because they are not numerous enough or efficient enough, waiting for planes that are not yet fuelled or warmed up. A passenger should be able to drive up to the aerodrome half an hour before the advertised time of departure, get weighed, and go straight to his allotted seat.

4. An agreement should be reached between countries on the main air routes to cut out all formalities that are purely irritative, and to cut out many of them altogether. At one part on the route to the Far East the flying-boat stops for an hour, and while it is refuelled the passengers are taken to a raft moored on the river for a cup of coffee. They do not go ashore, but they must line up to have their passports examined and their inoculation certificates checked up. Such a formality has no appreciable purpose beyond that of bloody-mindedness.

5. Hotels should be established at all important transit aerodromes and treated as extra-national territory. If passengers are confined to the building and checked only if they leave it, the formalities which make air travel wearying and exasperating can be cut out without risk. The structure and furnishings could be of the simplest, but each passenger should have a room and a bath, and there should be facilities for writing and posting letters and sending telegrams, and a few shops. While adjacent to the aerodrome, the hotel should be away from the refuelling site and the main runway ; one otherwise excellent air hotel is made impossible because planes tune up their engines all night outside the bedroom windows.

6. In flight, some small improvements would add to the interest of the traveller. Every purchaser of a ticket on these long-distance routes should be sent a written résumé of the main parts of the itinerary, to enable him to shop and pack for the journey. He should be told what extremes of temperature will be encountered, and what facilities there are for having linen washed. He should be given advice about money—e.g., travellers' cheques are of little value during the journey and B.O.A.C. currency coupons are essential. He should be advised on drugs—e.g., attacks of "tropical tummy" are very common, for which sulphaguanidine is an immediate and the only useful remedy. He should be warned that a fountain-pen cannot be used during flight. The passengers are naturally interested in the performance of the plane and the country over which they are flying; so a large-scale map of the day's course should be on the wall of the cabin, and a compass and air-speed indicator should be on the forward bulkhead. Writing-paper with the ship's name should be provided. An illustrated travel book of the route should be on sale, explaining the geographical and historical features of the country below, the climate and agriculture that account for the land features and the buildings on the ground, and the weather and trading or fishing habits that have produced the rigs that are seen in the harbours.

* * *

If you can't call an unregistered nurse "nurse" (as you won't be able to after Dec. 31) what the dickens can you call her? "Miss Smith," perhaps? Surely not. But already the nursing-homes have solved this one. They call them all "sister," which to most of us indicates a very superior person indeed.

poikilocytosis. Red-cell fragility normal. Serum bilirubin normal. No abnormality in urine and fæces. Radiography of chest normal.

The patient received immediate blood-transfusion (total 6 pints) and was later treated with large doses of iron, a high-protein diet, and vitamins. Her condition gradually improved and she gained weight; eight weeks later the hæmoglobin was 68% and the red cells numbered 3,700,000 per c.mm.

This patient's condition was due to gross nutritional deficiency, and had been aggravated by two pregnancies and by protracted breast-feeding. It would be interesting to know whether such severe anæmia due to inadequate diet has been seen elsewhere.

COAGULATION FACTORS

Sir,—In your annotation of April 12 you state that "the existence of an additional factor of the type postulated by Owren had already been suggested by the work of Frantl and Nance." As I am afraid that this statement might be misunderstood by those who did not study closely Dr. Owren's article (April 5), I want to draw attention to the fact that Owren quite independently —and as far back as in 1943[1]—not only discovered a fifth coagulation factor but also definitely proved its existence.

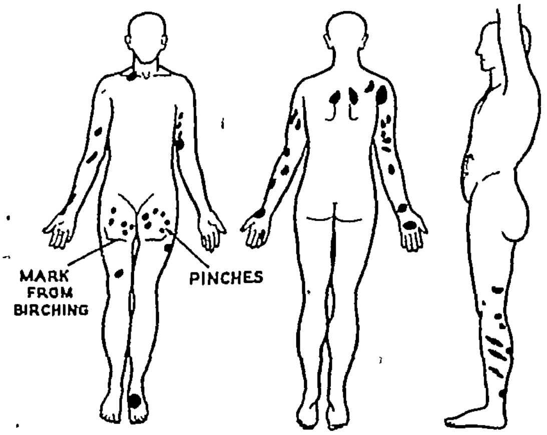
Central Laboratory, Aker Municipal Hospital, Ostre Aker, Norway. Karl Closs.

FEIGNED ERUPTIONS IN CHILDREN

Sir,—It has for long been recognised that hysterical women or malingerers may, with the object of obtaining sympathy or avoiding irksome duties, produce what have been called "feigned eruptions" or "dermatitis ficta," either by mechanical means or by the application of local irritants.

Such "eruptions" are to be distinguished from what may be called natural eruptions by their unusual shape and sharp outlines, and by the grouping and distribution of the lesions, which are found only upon easily accessible areas.

Eruptions of this sort have been usually regarded as very uncommon in children; as one writer has stated, "it would hardly be possible to think of deliberate self-mutilation in any but a very precocious child." Radcliffe Crocker, however, in his *Diseases of the Skin* mentioned the case of a girl of 7 who had longitudinal scabbed patches on the back of the phalanges, for which she had been sent several times to the seaside, which, as she confessed, she liked very much. Stopping the jaunts stopped the lesions, which were probably burns with a match. Moreover, many years ago, when I was a medical officer at Paddington Green Children's Hospital, there occurred a kind of epidemic of red streaks and excoriations upon the limbs of several children in a local school; it was discovered that these were produced by rubbing with a wet finger—a procedure probably accidentally discovered by one child and adopted by others from mere imitative naughtiness. These children had even found a title for their new and ex game—the mysterious name of "frog."



Rather more than thirty years ago there ap in a daily illustrated newspaper the diagram which reproduced here, with the following captions:

> "Alleged cruelty by dancing mistress to girl pupil doctor's diagram of alleged bruises."
>
> "When A.B., a dancing mistress, who totally d the allegation made against her, was summoned at the West London Police Court for ill-treating D.C., aged 1 *years, Dr. X,* in giving evidence, produced a chart illustrating the position of bruises on the child's body."

The girl was said to have run away from her teacher with another girl pupil, and in the witness-box to have stated that the dancing mistress had a cane and short stick when she was teaching.

The unfortunate dancing mistress was sentenced to several years' imprisonment—unfortunate because to any medical man with an expert knowledge of skin affections the shape, the grouping, and the distribution of the injuries as shown on the diagram would clearly indicate that they were self-inflicted, and with the object of avoiding an occupation which was uncongenial to the girl.

My reason for now calling attention to these somewhat rare examples of dermatitis ficta in children is to suggest the possibility that in some recent instances of supposed cruelty to children the injuries may have been due not to cruelty but to self-infliction; and that the opinion of a dermatologist would sometimes save unjust punishment of parents or of guardians of evacuees.

I am grateful to the *Daily Mirror* for allowing me to copy their illustration.

Bourne End, Bucks. H. G. Adamson.

STANDARDISATION OF SYRINGES

Sir,—The standardisation of syringes and needle-sockets is certainly much needed, but it seems a pity that certain points do not seem to have had the consideration they deserve. Thus it is proposed to abolish the 'Record' size and to standardise on a larger nozzle and needle-socket.

To many of us who use syringes and needles continually, this seems a retrograde step. The smaller nozzles afford in actual practice a much better fit, and there is no need to fix the needles so firmly on the syringe that they are difficult to remove. In many cases the larger glass nozzles never afford an airtight fit at all. For those of us whose work is concerned with the collection of specimens by aspiration, such a lack of fit is serious, as it leads often to frothing of the specimen and failure to obtain adequate amounts. I am aware that it may be answered that the collection of specimens is not the chief purpose of syringes, and that a small loss may not be of serious significance where an injection has to be made, though even here a bad leak may make much difference when such injections as those of insulin have to be given.

Furthermore, it may be said that two-piece glass syringes are to be encouraged as being easier to sterilise, and also that glass does not lend itself to making small-size nozzles. This is certainly the case, but the whole difficulty was avoided in the Jena glass syringes (obtainable before the war) in which a metal nozzle of similar coefficient of expansion to that of the glass was fused into the glass of the syringe. These were in every way excellent syringes—well-fitting and virtually indestructible. They could be sterilised by boiling, autoclaving, or dry heat (with the pistons in) up to temperatures of at least 150°C, and I have never known one to crack. In fact, I still have a number of them that have been in use for ten years; almost the only way to spoil them is to drop them in the sink.

It is surely not beyond the wit of man to make these syringes again, yet as far as I am aware they are not now available. There are several eminently suitable alloys for making such nozzles, with almost exactly the same coefficient of expansion as 'Pyrex' glass. Thus the alloys 'Fernico 2' and 'Kovar' have almost identical coefficients of expansion, and were actually invented to be fused into glass in this way. Some enterprising nshine, constitutional factors, vitamin deficiencies, and eruse of starch and sugar in the diet—I conclude that ey have little effect on endemic dental decay, and do t explain its peculiar geographical distribution. The nsistency of the food, the table-manners of the people, d the extent to which cutlery is used are far more portant.

---

[1] *Proc. Norwegian Acad. Sci.* 1944, p. 21.

The disuse odontoporosis which leads to dental caries n be prevented—and to some extent treated—by storing to the teeth their proper work of chewing. iough there is little immediate hope of getting the iite man to eat tougher food generally, this major ficiency of modern diets can be largely corrected by ding sufficient "toughage" to what we eat.

St. Albans, New York. H. H. NEUMANN.

STORIES OF ENDOCRINE RESEARCH

SIR,—Important discoveries have often been fortuitous. his Addison lecture Professor Dodds said that inkowski revealed the relation of the pancreas to abetes when he successfully performed pancreatectomy assistant to von Mering, who was interested in protein gestion.

I had the good fortune to meet Minkowski in Wiesden, shortly before his death, and one night after nner he told me how it happened. It was Hoppeeyler (then professor of physiological chemistry at rasbourg) who made the remark that the man who uld remove the pancreas from an animal and keep it ve would learn much about digestion, but it had been ied many times and no-one could do it. There ensued brisk discussion among the junior members of the hool after Hoppe-Seyler had left on holiday, and inkowski said that he could do the operation. Therepon a bet of 20 marks was made that he could not. e did it, and it was while they were drinking beer ought with the 20 marks and contemplating the dog nning about the laboratory yard that he noticed how ften the animal urinated and how a cloud of flies settled n the urine. It was then that he tested the urine and und sugar. When I asked Minkowski what part on Mering had in all this he said: "Oh, it was his dog."

That I should not be charged with the encouragement of etting and the drinking of beer for the promotion of ientific discovery, I think it proper to remark that in y judgment neither a good bet nor beer is a necessary relude. Pasteur said that chance favoured the mind hat was prepared.

Of the truth of Minkowski's story I have no doubt, or Naunyn in his memoirs says that Minkowski and on Mering had an argument whether a dog would urvive extirpation of the pancreas and "Mering hroughout the time he was in Strasbourg never did a ancreatectomy or even attempted it."

Birmingham. A. P. THOMSON

SIR,—I have read with interest the account of the ddison lecture by Professor Dodds in your issue of ay 24.

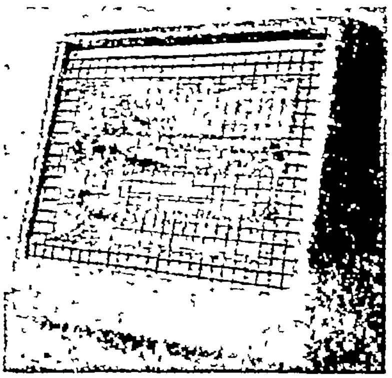
I was particularly interested in his description of the teps which led to the discovery of pancreatic diabetes y Mering and Minkowski. Both were at one time ssistants to Bernhard Naunyn, professor of medicine t Strasbourg, from whose account it appears that linkowski was mainly responsible for the discovery f the connexions between diabetes and the pancreatic land. The following is a translation from page 457 of Naunyn's Memoirs, published in 1925:

> "The experimental research on diabetes received a great impetus through the discovery of pancreatic diabetes by Mering and Minkowski. They had discussed pancreatectomy. Mering defended Claude Bernard's dogma that animals did not survive pancreatectomy. Minkowski, however, said that it was possible in dogs. I was asked my opinion I said, if one has been able to remove the liver, one should be able to remove the pancreas; and if geese can survive the former, dogs should survive the latter. The next day Minkowski carried out his first pancreatectomy, in my laboratory; Mering assisted and went on leave. When he re-entered the laboratory 24 hours later, Minkowski could already inform him that the dog had a severe diabetes with 5% sugar. By the way, Mering throughout the time he was in Strasbourg never did a pancreatectomy or even attempted it. He certainly never took part in the elaboration of the findings."

Leicester. F. E. ROSENTHAL.

DEATH IN THE FIREPLACE

SIR,—Dr. Leonard Colebrook in your issue of March 22 suggested an improvised grill guard fitted to the ordinary domestic electric heater, to reduce the possibility of clothing coming into contact with the heating element.



A guard of this type appears to be standard, if not compulsory, on all domestic heaters used in Germany. The illustration shows a typical heater used in the home. The wire grid is kept in position by being placed underneath a thin metal strip at the top and fitted loosely behind the front panel at the bottom. It is, therefore, easily removable to get at the elements, which are a good 2 in. behind the guard. Incidentally, the heater itself is constructed of cellulosed ply panels, and the reflector consists of aluminium foil on ply. As will be seen from the photograph there are no legs, and the shape of the heater is such that it is quite reasonably stable.

There appears to be no good reason why a heater of this design should not be made standard in this country and the provision of a guard be made compulsory for all heaters manufactured after a specified date. No doubt gas radiators could be designed on similar principles, with the distance between the guard and the heating elements adjusted accordingly.

V. FREEMAN
Town Hall, Islington, London, N.1. Medical Officer of Health.

***The *Islington Gazette* for May 16 records a St. Pancras inquest on a boy aged 5 years who was fatally burnt when his loose night-shirt was ignited by an electric fire. The fire was of the bowl type, and had "the usual guard as supplied by the makers with the mesh wire radiating from the central cone to the sides." The police witness said that this type of fire is not an open grate within the meaning of the Children's Fire Guard Act. Nevertheless, he added, they are "really dangerous things."—ED. L.

A RECORD LOW HÆMOGLOBIN?

SIR,—The following case is of interest as showing the very low hæmoglobin percentage that may be compatible with life.

A housewife, aged 32, was admitted to hospital with a history of weakness, increasing dyspnœa, palpitation, and tingling and numbness of the fingers and toes for the past 12 months. During this time she had also had ulcers on the edge of the tongue, which had prevented her from taking a normal diet. In the previous 2 years she had given birth to two children, both of whom were breast-fed. The last child was weaned at the age of 14 months, about 6 weeks before the patient's admission. There was no history of blood-loss.

On examination the patient was pale and emaciated, and her finger-nails were flat and brittle. Temp. 102°F, pulse-rate 110 per min., respirations 25 per min. The tongue was smooth, with pinpoint ulcers on the edges. Apart from a localised soft systolic murmur at the apex of the heart, no abnormal signs were found in the heart, chest, abdomen, or central nervous system. Blood-pressure 90/60 mm. Hg.

Blood picture: Hb 12% (1·7 g. per 100 c.cm.); red cells 607,000 per c.mm.; colour-index 1·0; packed-cell volume 5 c.cm. per 100 c.cm.; mean corpuscular volume 12 c.μ; mean corpuscular Hb concentration 34%; mean corpuscular diameter 8 μ; white cells 4100 per c.mm. (polymorphs 60%, lymphocytes 40%). A film showed gross anisocytosis and

One of his greatest contributions was his training and inspiration of younger men who came to him from all parts of this country and from abroad. There could be no better memorial than to continue this work which was so close to his heart: the training of young surgeons to build on the foundations he so securely laid.

It is proposed that a travelling scholarship shall be founded in Tudor Edwards's name, to enable suitable candidates to study thoracic surgery in special centres. This also will fulfil an urgent national need. For this purpose, a capital sum of at least £10,000 will be required. The Royal College of Surgeons and the Royal College of Physicians have agreed to administer the fund and carry out the conditions of the trust. Donations, and subscriptions under deed of covenant, should be sent to the hon. treasurer, Lord Courtauld-Thomson, at the Brompton Hospital, London, S.W.3.

MILK PRODUCTION AND GRADING

A South African View

SINCE returning to South Africa, E. J. Pullinger has specialised in milk-grading, first as a civilian and then as the officer of the South African Veterinary Corps responsible for the milk-supply of the army. His conclusions on the principles of grading and methods of improving the milk-supply [1] [2] are of general interest.

STANDARDS

He agrees with Wilson et al.[3] about the inaccuracy of the plate test and the value of the methylene-blue reduction test, and points out that in any event the plate test is too cumbersome to perform on a sufficient scale. The advantages of the Breed test are that it immediately provides information which will prevent bad milk being mixed with good milk, and that it reveals herd infection with mastitis.

A far clearer picture of "dairy hygiene" or "keeping quality" is obtained from an approximate test done frequently than from a very accurate test which, because of its complexity, can only be done occasionally. Pullinger therefore recommends that every herd should be tested five times a week, but points out that this leads to the accumulation of a mass of figures which are quite useless unless a satisfactory method of analysis can be devised. He concludes that any form of direct mathematical analysis of results is foredoomed to failure, because fundamentally it is a fallacy to weight good results too heavily with the bad ones. The consumer is concerned with the quality of the milk he receives each day, and he would judge the quality of his supply by comparing the number of times the supply was good with the number of times it was bad: put another way, his milk does not suddenly go sour in his porridge plate because he remembers that last Sunday the supply was badly tainted. Even the most careful and enthusiastic producers have some bad results, and testing authorities use their "discretion" before taking action; but to lay down a strict numerical standard and then to apply that standard upon a discretionary basis spells disaster to both the value of the standard itself and to any grading scheme.

In order to overcome these difficulties Pullinger advises the use of the "good-bad" ratio. He proposes, as an arbitrary division between good and bad, a Breed count of 1,000,000 and a methylene-blue reduction time of 3¾ hours: any test result better than these figures is classed as good and any worse than this as bad. In the winter there was a good correlation between results of the methylene-blue reduction test and Breed count, but in the summer this correlation b down. The fact is discussed in relation to the "lat defect" of milk and it is suggested that all milk sho be 8–12 hours old before being tested.

The highest standards likely to be obtained in So Africa are:

Summer (September to March) good-bad ratio .. 2:1
Winter (April to August) good-bad ratio 5:1

Though this standard may seem low, very few So African producers can maintain it.

In criticism of the good-bad ratio it may be argu that a producer who regularly gives a count of 900,0 is classed as always good, while another producer givi a count of 1,020,000 is always bad. This objection admitted, but it is one which cannot be escaped grading. Whatever grade or figure is chosen, th producer who just exceeds that figure is always unfair treated, compared to those who just make the grad As an objection, however, it is purely theoretical, becau in practice producers never do give results consistentl just above or just below any given level. Howeve good the producer, his results will fluctuate, and the good- bad ratio system shows whether the fluctuations pre dominate on the good or the bad side of the given lin The principle, it is suggested, might well be applied to a forms of milk grading.

INCENTIVES AND COERCION

It has been proposed in these columns [4] that a dairy licence should be granted on the farmer's ability to produce satisfactory milk, and not on an arbitrary building standard. Discussing this subject, Pullinger says that, broadly, the dairy farmer and dairyman require to be industrious, clean, honest, and intelligent, these characters being listed in order of importance.

> "The dairyman must be continually controlling the work in the stable, milk-room or shop and he must control it every day and every night. Dairying cannot be controlled from the stoep, nor can control be considered t exclude night and week-end duty, public holidays and a annual holiday at the coast. In other words, dairying i an unending grind which can only be relieved by a satisfactory partnership, in which case the business has t support two partners."

This remark applies equally to Great Britain, and should be read in conjunction with the recent pleas for increasing the financial rewards of food-producers.[5]

It has previously been pointed out [6] that without adequate recompense farmers and their men will no undertake the onerous work of milk-production. Standards of production in South Africa are tending t *fall rather than improve*, because the value of land, farms, and dairy stock has risen so much that genuine dairy farmers have tended to sell out, leaving the work o milk-production to the beginner.

Pullinger deprecates, for South Africa, the legal coercive method of improving the milk-supply. It is he says, largely ineffective, and it operates more effectively against the poor man than against the rich. The poor man has to accept the controlling authorities' laboratory findings as correct, and has to face convictio before a magistrate. The rich man can afford to have control tests done, and by employing skilled lega representation—and if necessary by appealing to a higher court—he may well escape conviction through some legal quibble. Ultimately the controlling authority ceases to prosecute such a person, because *it is a waste of time.*

The normal routine of efficient agricultural or commercial marketing is to price the product according to its quality (including nutritional value), and it is hard to see why milk should be placed in a different category. Pullinger suggests that the bonus-earning standards of cleanliness could be based on either the Breed count or (preferably) the methylene-blue reduction test.

The bonus grades nos. 1 and 2 would be based on good-bad ratios increasing in severity every two years. The highirm could certainly manufacture syringes from these ubstances.

Apart from the question of fit, glass nozzles are lways very vulnerable to fracture, not only from actual reaking off of the nozzle, but also from minor trauma o the point, which causes a minute sliver of glass to detach itself from the side of the nozzle, thus destroying the fit of the needle.

I should like, therefore, to make a plea for the retention of the Record size of nozzle, which is adequate for any needle-bore in current use. If fused-in nozzles are used this does not prevent two-piece glass syringes from being made; and in this manner all difficulties of sterilisation will be avoided. That syringes capable of sterilisation at autoclave temperature are essential was underlined in the course of a recent law-case,[1] though personally I prefer dry sterilisation in a hot-air oven at 180°C, which calls for even greater care in construction.

It may be well to bear in mind that the Record size is at the present time by far the most commonly used; it should not be lightly discarded.

London, W.1. J. W. SHACKLE.

POSTOPERATIVE PROGRESSIVE BACTERIAL SYNERGISTIC GANGRENE

SIR,—In his paper of May 31 (p. 748), reporting a case of postoperative progressive bacterial synergistic gangrene successfully treated with penicillin, Mr. Clarke describes the micro-aerophilic non-hæmolytic streptococcus as derived from the intestinal or respiratory tract. I have found that, in a susceptible person, a surgically clean incision is all that is required to start the process; no connexion with the gut or respiratory apparatus is necessary. Mr. Clarke also writes: "Before the introduction of penicillin the only treatment was a radical excision of the affected area well beyond the spreading zone of hyperæmia. . . . The wound was then smeared with 'active' zinc-peroxide paste. . . . Many of the reported cases which recovered were treated without peroxide, which is probably unnecessary provided the excision is radical enough. . . ." Without attempting to depreciate the value of penicillin in these cases may I point out that there is another "oxidising agent" the local application of which has arrested the spreading process and enabled rapid healing to occur, without any necessity for skin-grafting, in one (unpublished) case in England and more than one case abroad? No excision is required with this remedy; I refer to potassium permanganate, applied as a dry powder and covered by a 'Vaseline' dressing.

St. Margaret's Hospital, Epping. FRANK MARSH.

PREVENTIVE OPERATION FOR POSTOPERATIVE THROMBOSIS

SIR,—To what lengths can prophylactic surgery be taken? When is it justifiable to operate to prevent a possible but uncertain complication? The recent literature on postoperative thrombosis suggests that across the Atlantic there is a more liberal attitude towards preventive operations than in this country.

Allen[2] reports on 458 prophylactic bilateral superficial femoral-vein interruptions done at the Massachusetts General Hospital in the period January to October, 1946. The vein is ligatured on both sides immediately distal to the profunda tributary. The operation is done under local anæsthesia, and the bilateral procedure takes about an hour. It was done in patients beyond the age of 65 at the time when, or within forty-eight hours after, bed rest became necessary. The author admits that not all his colleagues at the hospital have been convinced to date of the value of prophylactic bilateral femoral-vein ligation, but he demonstrates its value by analysing a comparable series of cases where no ligation was performed and where the incidence of phlebitis and fatal embolism was much higher.

This study cannot but amaze Allen's British colleagues. Few British surgeons can have seen so many cases over 65 during ten months of one year on whom they would consider ligating both femoral veins for what is a disastrous but not so very common complication. If Allen is to be interpreted correctly he includes this ligation as a part of the routine preoperative preparation of his elderly patients.

Another even more amazing study is by Thebaut and Ward,[3] who report on 36 patients treated by ligation of the inferior vena cava within the past three years. To prove the dangers of pulmonary embolism they quote McCartney's figures in which pulmonary embolism was found to account for 5·3% of 4070 postoperative deaths. In their series 4 patients died, 2 during the induction of anæsthesia and 2 within a few hours of the operation, a case-mortality of 11%. The severe complications included 1 incisional hernia and 2 intestinal obstructions. All these ligations were done after one or more non-fatal embolic episodes—a selected group of patients in whom it has been shown at the Mayo Clinic that there is a 20% risk of a fatal embolism following.

Here are two challenges. Are we to ligate both femoral veins in all elderly patients when they are confined to bed, and are we to ligate the inferior vena cava in all cases of non-fatal pulmonary embolism? The natural British conservatism is repelled by this enthusiasm for prophylactic surgery, but before condemning our colleagues' latest contributions it would be as well for large hospitals in this country to review *and publish* their morbidity and mortality figures for postoperative venous complications, so that it can be judged whether the problem is of the same magnitude as in America and whether it requires the same radical and dramatic solution.

Bath. S. GLASER.

CLIMATE AND RHEUMATISM

SIR,—In your issue of May 24 Dr. Kenneth Stone refers to the notorious effect of climatic changes in provoking rheumatic pains. Now why is it that this matter has not been more fully investigated? To me it seems of fundamental importance. We admit that such changes may induce pain, but I have yet to hear of any adequate scientific investigation which might not only make clear the ætiology but give a pointer to treatment.

At the risk of being tedious I would point out that such pains are presumably not due to changes of pressure alone, nor to changes of temperature alone, nor to changes of humidity alone. But these three together, perhaps with changes in atmospheric ionisation, appear able to upset the delicate balance of those who are susceptible. Surely experiment would not be difficult? Before the war I saw in Germany a testing chamber (used to assess the fitness of airmen for their work) which was provided with devices for changing pressure, temperature, humidity, and ionisation.

There is no doubt that cold is a factor. Vigorous young men, for the sake of money, take employment in the frozen-meat stores in the Argentine; many are crippled by rheumatism after a few years' work.

Colchester. G. C. PETHER.

TUDOR EDWARDS MEMORIAL

SIR,—The remarkable progress of chest surgery in this country is in large measure due to the work of Arthur Tudor Edwards, who died last August at the age of 56. His pioneering in this branch was in the main the chief stimulus to its expansion. His singleness of purpose, and the high standard which he set for himself and all those who worked with him, raised a small but important branch of surgery to its present position as one of the great surgical specialties. As the result of this development, men and women have been restored to life and health for whom previously medical science offered no effective aid.

Tudor Edwards literally devoted his life to his work. He was unsparing in his service to his patients in all walks of life, and many came to him from other countries. On the outbreak of war, in addition to his other work, he undertook the organisation of thoracic surgery for the Emergency Medical Service of the whole country and for the Army and Royal Air Force. He carried this heavy burden throughout the war, despite the gravest warnings and with the full knowledge that his life thereby would be shortened.

Diary of the Week

JUNE 8 TO 14

Monday, 9th

Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
3.45 p.m. Mr. R. J. Last: Pectoral Girdle. (Arnott demonstration.)
5 p.m. Mr. T. Keith Lyle: Squint Surgery.

Medical Society of London, 11, Chandos Street, W.1
8 p.m. Clinical meeting.

Fellowship of Postgraduate Medicine
5 p.m. (Rheumatism Unit, St. Stephen's Hospital, Fulham Road, S.W.10.) Dr. Hugh Dunlop: Endocrine Factors in Relation to the Chronic Rheumatic Diseases.

Tuesday, 10th

Royal College of Surgeons
5 p.m. Dr. Alice Carleton: Skin Disease in Relation to Ophthalmology.

Royal Society of Medicine, 1, Wimpole Street, W.1
8 p.m. *Psychiatry.* Prof. L. S. Penrose: Importance of Statistics in Psychiatry.

Fellowship of Postgraduate Medicine
5 p.m. (St. Stephen's Hospital.) Dr. E. G. L. Bywaters: Joint Physiology and Pathology.

London School of Dermatology, 5, Lisle Street, W.C.2
5 p.m. Dr. I. Muende: Fungus Infections of the Skin.

Edinburgh Post-Graduate Board for Medicine
5 p.m. (Royal Infirmary.) Mr. C. P. Stewart, ph.d.: Biochemistry of Senescence.

Wednesday, 11th

Royal College of Surgeons
3.45 p.m. Mr. R. J. Last: The Larynx. (Arnott demonstration.)
5 p.m. Mr. F. A. Williamson-Noble: Glaucoma Surgery.

Fellowship of Postgraduate Medicine
5 p.m. (St. Stephen's Hospital.) Mr. Timbrell Fisher: Orthopædic Aspect of the Chronic Rheumatic Diseases.

Thursday, 12th

Royal College of Surgeons
5 p.m. Mr. J. Minton: Occupational Eye Diseases and Injuries. (Hunterian lecture.)

Royal Society of Medicine
4.30 p.m. *Ophthalmology.* Demonstration of methods of illumination.
5.15 p.m. Mr. J. G. D. Currie, Mr. H. C. Weston, Mr. J. W. T. Walsh, d.sc.: Illumination.

Fellowship of Postgraduate Medicine
5 p.m. (St. Stephen's Hospital.) Dr. David Shaw: Psychogenic Rheumatism.

London School of Dermatology
5 p.m. Dr. H. W. Barber: Prurigo.

Edinburgh Post-Graduate Board for Medicine
4.30 p.m. Dr. R. W. D. Turner: Judgment in Cardiology—a Study of Errors. (Honyman Gillespie lecture.)

Friday, 13th

Royal College of Surgeons
3.45 p.m. Mr. R. J. Last: Kidneys. (Arnott demonstration.)
5 p.m. Prof. W. J. B. Riddell: Hereditary Eye Disease.

Royal Society of Medicine
10 a.m. Pædiatrics. (Royal Victoria Infirmary, Newcastle.) Prof. J. C. Spence: Organisation of a Professorial Unit. Dr. Mary Taylor: Method of Recording Neonatal Infections in a Maternity Hospital. Dr. F. J. W. Miller: Prematurity in an Industrial Town.
2.15 p.m. Dr. Alan Ogilvie: Bronchiectasis. Dr. Donald Court: Acute Intussusception.

Fellowship of Postgraduate Medicine
5 p.m. (St. Stephen's Hospital.) Dr. Philip Ellman: General Medical Diagnosis in Relation to the Chronic Rheumatic Diseases.

Empire Rheumatism Council
4.30 p.m. (Apothecaries Hall, Blackfriars Lane, E.C.4.) Sir Adolphe Abrahams: Inaugural lecture.
5.30 p.m. Dr. Ernest Fletcher: Arthritis.

Saturday, 14th

Empire Rheumatism Council
10 a.m. (Apothecaries Hall.) Dr. R. E. Bonham-Carter: Juvenile Rheumatism and Still's Disease.
11.15 a.m. Dr. G. D. Kersley: Spondylitis.
2 p.m. Dr. George Graham: Gout.
3 p.m. Dr. W. S. C. Copeman: Non-articular Rheumatism and Sciatica.
4.30 p.m. Dr. Oswald Savage: Differential Diagnosis of Arthritis. (Course ends Sunday.)

For Doctors Only is a collection of twelve sketches of general practice by "Hugh Selwyn" which first appeared in the *London Hospital Gazette*. It entirely avoids the solemnity of Victorian studies on the same theme: but, like the characters, it "sobers down at times for clinical reasons," and readers with a high tolerance for exuberance, slang, and anecdote will find useful information among the fun. It is published by W. E. Harrison & Sons, Ltd., Ipswich, at 5*s*.

Notes and News

FOR NURSING CANDIDATES

Brochures from nurse training schools are now the fashion. St. George's Hospital has published a han and well-illustrated document describing the training of and the amenities of the two nurses' homes. Nurses spend a period of training in the Atkinson Morley Hospi a branch of St. George's, which, besides being used for valescence and reablement, also houses large neurosurgi and psychiatric departments.

The training schools of large voluntary hospitals are in position to select candidates, and it is noteworthy that th brochure begins by outlining qualifications which "candid must necessarily fulfil." They should be "of good educat health and physique, and they should have the nat *temperament which makes for the successful nurse.*" T slightly discouraging opening may be contrasted with t note on education found in a brochure issued by Brom and District Hospital: "There is full scope in the nur profession for girls of marked ability and high educatio standard, but the girl who has, for one reason or anoth not gained a school certificate need not feel that she is debarr from acceptance as a student nurse on this account."

Both brochures set out clearly the facts about nur examinations, and outline the careers and prospects op to the qualified nurse. Such publications should do mu to give prospective candidates a balanced view of the nur life, and to correct misgivings about conditions of work an living quarters in good modern training schools.

FOR PSYCHIATRIC SOCIAL WORKERS

The mental-health service depends much on the ability and initiative of psychiatric social workers. The London School of Economics, with the help of the Maudsley Hospital staff, have long undertaken the training of metropolitan social workers in this specialised branch; and the London County Council have just published a handbook[1] for the guidance of psychiatric and mental-deficiency workers in their public-health department.

This handbook, compiled by a special committee of experienced officers of the council, was largely in proof before the National Health Service Bill was introduced last year; and the committee had to decide whether to give up the book for the moment, or to proceed with it, delaying final publication until the Act was passed. The second course was chosen, and since the main effect of the Act has been to transfer the control of mental hospitals, mental-deficiency institutions, and psychiatric outpatient clinics to regional hospital boards, it has been possible to indicate the changes which will follow when the Act comes into force. The local health authorities remain responsible for the ascertainment of cases of mental deficiency and mental ill health, for statutory supervision and guardianship of mental defectives living in the community, and for aftercare. The handbook covers these and other aspects of work in which the psychiatric social worker shares, including the procedure for obtaining detention orders, guardianship, psychiatric social work in mental hospitals, mental-deficiency institutions, observation wards and outpatient clinics, and the special problems presented by old age and epilepsy.

The chapter on guardianship mentions a recent practice by which social workers on the council's staff have been made the statutory guardians of defectives. This is a specially satisfactory way of looking after mentally defective boys who have left a residential special school at the age of 16. The appointment of a social worker as guardian enables the council to supervise such boys more closely than would otherwise be possible; and though it entails serious responsibility for the social worker she usually finds it a satisfying piece of work giving scope to her best qualities. Her first task is to find suitable lodgings for the mentally defective boy, with a landlady who will take an interest in his personal care and welfare. It is found that a household with a man at the head usually suits this type of boy better than one in which the atmosphere is wholly maternal. The handbook advises on the kind of home to be chosen, and on the sort of life the boy should be encouraged to lead, as well as much other important information. It is marred only by a somewhat stilted choice of style and language.

---

[1] Handbook on Mental Health Social Work. County Hall, Westminster Bridge, S.E.1. Pp. 111. 2*s*. 6*d*.

de bonus no. 3 would be comparable to the overseas rtified" grade. Milk to be classed as high-grade would ,à to comply with no. 3 standards in respect of cleanliness, ter-fat and solids-not-fat. Furthermore it would have to e from herds free from tuberculosis, contagious abortion l paratyphoid infection, and having a restricted allowable centage of mastitis-infected cows (it should be noted that is a higher standard than any imposed in Great Britain). is allowable percentage of chronic mastitis carriers might temporarily established between 5% and 10%, but the ition would probably have to be reviewed later.

A MILK CORPORATION

No system of grading can be effective unless all milk purchased by a single authority, comparable (but not essarily similar) to the British and Scottish milk rketing boards. A weakness of the British scheme is it, as it is primarily designed to protect the financial erests of the producer, it pays relatively less attention the safety and quality of milk. Moreover though the ard is responsible for the production end of the industry, ler authorities remain in control of pasteurisation d the manufacture and distribution of milk and milk oducts.[7] In other words an organisation similar to e British board would not be in a position to implement more than a few of the recommendations made Pullinger. In its stead, therefore, he suggests a blic-utility corporation which would establish collecting pots at strategic points in milk-producing areas, gether with processing depots, laboratories, and ministrative offices in the towns. The organisation uld have to be self-supporting and not dependent on vernment subsidy. It would collaborate with the alth authorities, and could do much to assist in the ntrol of animal diseases.

Pullinger emphasises the importance of proper grading milk before pasteurisation. He concludes that the actice of distributing pasteurised milk in bulk is highly ngerous; it should be bottled, sealed, and stored under frigeration.

This Year's Smallpox

From the beginning of the year up to June 3 the inistry of Health has been informed of 59 confirmed ses of variola major. This compares with 56 for the hole of 1946, which was the highest incidence since '34 (179 cases, mainly variola minor). The 1947 cases ve arisen from two distinct sources. The first, which as not identified, resulted in 15 cases in two generations a common lodging-house and public-assistance hospital Grimsby, Lincs, their dates of onset being between eb. 16 and March 2. The second source was a highly odified attack in a soldier flown home from India compassionate leave. He developed the disease at lston, Staffs, on March 2, having landed in England Feb. 23.

Cases in direct succession to these two sources are still ising. The present outbreak at Barnsley, in the West iding of Yorkshire, is almost certainly related to the rimsby episode. The infection introduced from India ntinues to produce cases in Bilston and in the adjacent istrict of Coseley.

Associated with the Grimsby source there have been ci at Stepney (2 cases in two generations), Scunthorpe, incs (7 cases in two generations), and Doncaster, Yorks case); but these appear to have been eradicated. In onnexion with the Bilston source a single case occurred Birmingham on May 1. Three cases in two generations t Sheffield may also have been associated with Bilston. atients were removed during the week ending May 31 t Barnsley, Bilston, and Coseley.

Barnsley.—The first generation numbered 5 cases (3 eaths) at Barnsley and 1 at Bermondsey. There has been o spread from this latter case, undoubtedly because f the prompt action taken by a practitioner who diagosed the disease at sight on the first day of rash. The econd generation at Barnsley so far numbers 4 detected nce May 29. They are in the line of contact either at he common lodging-house (24A, Doncaster Road) or t. Helens Hospital and do not indicate that the disease is out of control. The only alarming feature is that some of the common lodging-house contacts have not been traced and may give rise to other foci, particularly along the tramp routes across England through Lincolnshire, West Riding of Yorkshire, Derbyshire, Cheshire, and Lancashire.

Bilston and Coseley.—The mother and sister of an unvaccinated girl who died on May 16, four days after onset, were removed to a smallpox hospital on May 31 (onsets May 29 and 30). The mother of a kitchen-maid at Moxley Infectious Diseases Hospital, removed from her home in Coseley on May 19, has now developed the disease (onset May 28, rash and removal May 30).

Infectious Disease in England and Wales

WEEK ENDED MAY 24

Notifications.—Smallpox, 8; scarlet fever, 782; whooping-cough, 1879; diphtheria, 197; paratyphoid, 6; typhoid, 3; measles (excluding rubella), 12,830; pneumonia (primary or influenzal), 557; cerebrospinal fever, 65; poliomyelitis, 11; polioencephalitis, 2; encephalitis lethargica, 0; dysentery, 47; puerperal pyrexia, 135; ophthalmia neonatorum, 61. No case of cholera, plague, or typhus was notified during the week.

Of the 8 cases of smallpox 3 were reported at Barnsley, 2 at Grimsby, 1 at Sheffield, 1 at Bilston, and 1 at Coseley.

Deaths.—In 126 great towns there were no deaths from enteric fever or scarlet fever, 5 (1) from diphtheria, 6 (0) from measles, 15 (2) from whooping-cough, 76 (12) from diarrhœa and enteritis under two years, and 9 (0) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 261 (corresponding to a rate of 25 per thousand total births), including 32 in London.

Obituary

CARL BRUCK

M.D. MUNICH

NEWS has now been received of the death three years ago of Prof. Carl Bruck, who, with Wassermann and Neisser, in 1906, described the specific diagnostic blood-test for syphilis. He was born in 1879 at Glatz, in Silesia, and after graduating in 1902 he spent four years as an assistant at the Robert Koch Institute in Berlin. In 1906 he joined the German expedition for the investigation of syphilis in Java. On his return to Germany in 1908 he was appointed to the university dermatological clinic at Breslau under Neisser, and three years later received an associate professorship. Later he became director of the dermatological department of the municipal hospital in Altona, and he held this position until he was removed by the Nazis in 1933. He died by his own hand on June 12, 1944, when he was about to be arrested by the Gestapo, and his wife (née Olga Jebsen) followed him two days later.

Births, Marriages, and Deaths

BIRTHS

GRAY.—On May 26, in London, the wife of Dr. J. D. Gray—a son.

KING.—On May 13, the wife of Dr. R. E. King—a daughter.

LUMB.—On May 31, in London, the wife of Dr. George Lumb—a son.

MILLER.—On May 28, at Newcastle-upon-Tyne, to Dr. Eileen Miller (née Baird), wife of Dr. Henry Miller—a daughter.

RODGERS.—On May 27, the wife of Mr. Harold Rodgers, O.B.E., F.R.C.S.—a son.

STROTHER-STEWART.—On May 24, at Edinburgh, the wife of Dr. C. R. Strother-Stewart—a son.

TOOMEY.—On May 25, at Arbroath, the wife of Surgeon Lieut.-Commander A. Toomey, R.N.—a daughter.

MARRIAGES

PATUCK—MAYHALL.—On May 24, at Luton, Framjee Patuck, M.R.C.S., to Margaret Mayhall.

DEATHS

DOCKRAY.—On May 27, at Bournemouth, John Smalley Dockray, M.D. Manc., B.Sc. Lond., aged 76.

LITT.—On May 25, at Lytham St. Annes, John Percy Litt, M.D. Edin., D.P.H., D.T.M. & H., colonel R.A.M.C.

MACDONALD.—On May 28, at Edinburgh, Angus Graham Macdonald, O.B.E., M.D. Edin.

WHELAN.—On May 27, at Plymouth, Hamlet Mark Whelan, M.R.C.S., surgeon rear-admiral R.N.

University of Oxford

On July 26 the honorary degree of D.SC. will be conferred on Dr. A. E. Barclay.

Royal College of Physicians of London

On Tuesday and Thursday, July 15 and 17, Prof. P. C. P. Cloake will deliver the Humphry Davy Rolleston lectures at the college, Pall Mall East, S.W.1. He will speak on the Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic.

London Blood Transfusion Service

The headquarters of the Greater London Blood Transfusion Service are now at 10, Collingham Road, S.W.5 (Frobisher 6477).

Research Defence Society

On Tuesday, June 17, at 3.15 P.M., at 26, Portland Place, London, W.1, Prof. G. H. Wooldridge, F.R.C.V.S., will deliver the Stephen Paget lecture on What Animals Owe to Experimental Research.

Passano Foundation Award

On June 12 in Atlantic City this award for 1947 will be presented to Mr. Selman A. Waksman, microbiologist at the New Jersey Agricultural Experiment Station, by Mr. Robert S. Gill, president of the Williams & Wilkins Company and of the foundation. Mr. Waksman will afterwards give an address on Antibiotics and Tuberculosis—a Microbiological Approach.

Royal Medical Foundation of Epsom College

Henry Duncalfe annuities of £30 p.a. each for spinsters in need of help will shortly be awarded by the council. Candidates must be daughters of registered medical practitioners and must have attained the age of 50. Pensions for impecunious doctors or their widows, and scholarships for their sons, are also available from the funds of the foundation. Forms of application may be had from the secretary, Epsom College, Surrey.

Hospital for Sick Children, Great Ormond Street

Members of the consulting staff of the hospital will in future see outpatients only by appointment. Appointments, which should be made by the patient's own doctor, preferably in writing, may be made for any time between 9.30 A.M. and 12.30 P.M. except on Sundays. Patients who attend without an introduction from a doctor will be examined in the receiving-room, and only when necessary referred to a consultant.

Society for Relief of Widows and Orphans of Medical Men

The annual general meeting of the society was held on May 21, with Dr. R. A. Young, the president, in the chair. The resignation of Dr. Blackett was received, and in appreciation of his services as secretary for over 40 years he was elected a vice-president. During 1946 £4950 was distributed to the 52 widows who are beneficiaries. The membership of the society is now 281, of whom 160 are life members and 121 are ordinary members. Further particulars may be had *from the secretary, 11, Chandos Street, London, W.1.*

Central Drugs Laboratory for India

Under the Drugs Act the Biochemical Standardisation Laboratory at 10, Chittaranjan Avenue, Calcutta, has been constituted as the Central Drugs Laboratory. Its functions will include: (1) the analysis of samples submitted by customs collectors and courts of law, and (2) the granting of certificates of registration for patent and proprietary medicines with undisclosed formulæ. The Drugs Act and rules came into force on April 1, except the provisions for the registration of patent and proprietary medicines, which are to take effect on April 1, 1948.

British Empire Leprosy Relief Association

Dr. Gordon Ryrie has been appointed medical secretary of the association in succession to Dr. Ernest Muir who has retired.

Dr. Ryrie, who graduated M.B. at the University of Edinburgh in 1926, joined the Colonial Medical Service in Malaya two years later. He was appointed superintendent of Sungei Buloh Leper Hospital in 1930, where he remained until the end of 1945. During the Japanese occupation Dr. Ryrie organised his settlement as a base for aiding our troops, guiding them in the jungle and sending food and medical supplies. In January, 1944, the Japs became suspicious, and they put him in prison, later sending him to a labour camp where he remained until the liberation. Immediately after VJ-day, though in poor health, he resumed his work at the Sungei Buloh Hospital until the autumn of 1945 when he returned to England.

Society for Endocrinology

The following officers of this society have been chairman, Mr. A. S. Parkes, SC.D., F.R.S.; secretary, Mr. Folley, PH.D.; treasurer, Mr. C. W. Emmens, PH.D.; of the *Proceedings*, Prof. S. Zuckerman, F.R.S.; members committee, Dr. P. M. F. Bishop, Dr. C. H. Gray, Mr. P. Williams, Prof. F. G. Young, D.SC.

Return to Practice

The Central Medical War Committee announces that Harold Park, F.R.C.S., has resumed civilian practice 40, Wilbury Road, Hove, 3, Sussex.

Foreign Awards

The following decorations have been conferred on R.A.M.C. officers in recognition of distinguished services in the cause the Allies:

UNITED STATES

Legion of Merit.—Major-General W. C. Hartgill, C.B., M.C., K.H.S. (commander); Brigadier D. B. McGrigor, O.B.E. (officer).

Bronze Star Medal.—Lieut.-Colonel A. J. King, Major H. G. McQuade.

BELGIUM

Croix de Guerre 1940 *with Palms.*—Captain R. L. Rees.

CZECHOSLOVAKIA

Order of the White Lion (3rd Class).—Major-General Sir Henry Tidy, K.B.E.

Medal for Merit (1st Class).—Lieut.-Colonel Henry Ross, C.I.E., I.M.S.

Appointments

BALL, MARGARET, M.B. Camb., M.R.C.P.: asst. physician, the Elizabeth Garrett Anderson Hospital, London.

BRASH, DAVID, M.B. Glasg., D.M.R.: radiologist, Bolton Royal Infirmary.

BURT, H. A., M.B. Camb., M.R.C.P.: director of department of physical medicine, University College Hospital, London.

BYARS, J. R., M.B. Aberd., D.P.H.: senior asst. county and school M.O., Leicestershire.

DAVIES, I. G., M.D. Lond., M.R.C.P., D.P.H.: M.O.H. and school M.O., Leeds.

DOYLE, W. J., M.B. N.U.I., D.P.H.: deputy county M.O.H., Devon.

GEOHEGAN, V. P., M.B. Leeds, D.P.H.: deputy M.O.H., Weston-super-Mare.

HEWITT, SELWYN, M.B. Durh., B.HY., D.P.H.: senior asst. county M.O. and school M.O., Herefordshire.

KATZ, JACOB, M.D. Bratislava, D.P.H.: deputy M.O.H., Accrington.

LOUIS, FRANCIS, M.B. Lond., F.R.C.S.: accident and orthopædic surgeon, Great Western Hospital, Swindon.

PURDIE, A. W., M.B. Glasg., F.R.F.P.S., M.R.C.O.G.: obstetrician, North Middlesex County Hospital, Edmonton.

ROSE, MURIEL, M.B. Lond., M.R.C.O.G.: obstetrician, Redhill County Hospital, Edgware.

SHAW, C. H., M.B. Lond.: asst. M.O.H., Rotherham.

THORBURN, A. L., M.D. Belf., D.P.H.: senior asst. M.O., East Riding, Yorks.

TURNEY, H. F., D.M. Oxfd, M.R.C.P.: physician i.c. department of physical medicine, Southend-on-Sea General Hospital.

London County Council Mental Health Service:

Asst. medical officers:

- **AMINOFF, JACK**, M.R.C.S.: Friern Hospital, New Southgate.
- **ANNEAR, M. W.**, M.R.C.S.: Cane Hill Hospital, Coulsdon.
- **JONES, R. M.**, M.B. Camb.: Banstead Hospital, Sutton.
- **MAY, P. R. A.**, M.B. Camb.: Bexley Hospital, Bexley.

Royal Berkshire Hospital, Reading:

- **EVANS, W. G.**, M.B. Lond., D.M.R.T.: director of radiotherapy department.
- **HOOPER, A. N.**, M.B. Camb., F.R.C.S.: obstetrician and gynæcologist.
- **WILLIAMS, R. H. H.**, M.B. Camb., F.R.C.S.E.: aural surgeon.

Royal Victoria Infirmary, Newcastle-upon-Tyne:

- **BLACK, J. I. M.**, M.D. Durh., F.R.C.S.: asst. surgeon to throat, nose, and ear department.
- **BRUMWELL, JOHN**, M.B. Durh., F.R.C.S.: surgeon.
- **DAVISON, GEORGE**, M.D. Durh., M.R.C.P., D.C.H.: associate physician, children's department.
- **DEWAR, H. A.**, M.D. Durh., M.R.C.P.: asst. physician.
- **GREEN, C. A.**, M.D., PH.D. Edin., D.P.H.: clinical bacteriologist.
- **HOUSTON, B. D.**, M.B. Durh., D.M.R.: asst. radiologist.
- **HUNTER, WILLIAM**, M.D. Durh., M.R.C.O.G.: associate surgeon, gynæcological department.
- **JONES, J. D. T.**, M.S. Durh., F.R.C.S.: asst. surgeon.
- **LAKE, L. H.**, M.B. Durh., D.O.M.S.: asst. surgeon, ophthalmic department.
- **MILLER, H. G.**, M.D. Durh., M.R.C.P., D.P.M.: asst. physician.
- **MILLER, J. F. W.**, M.D. Durh., M.R.C.P., D.C.H.: associate physician, children's department.
- **PASK, E. A.**, O.B.E., M.B. Camb., D.A.: head of department of anæsthetics.
- **RANKEN, MARGARET**, M.B. Durh.: associate surgeon, ophthalmic department.
- **REID, J. L.**, B.M. Oxfd, D.L.O.: asst surgeon, throat, nose, and ear department.
- **ROSE, J. D.**, M.B. Durh., F.R.C.S.: asst. surgeon.
- **STABLER, F. E.**, M.D. Durh., F.R.C.S., F.R.C.O.G.: asst. surgeon, gynæcological department.
- **WAY, S. A.**, M.R.C.S., M.R.C.O.G.: associate surgeon, gynæcological department.
- **WRIGHT, ELSIE**, M.D. Lond.: associate physician, children's department.

MEDICAL DIRECTORY

This invaluable work[1] has undergone an operation in its 3rd year. It had become so unwieldy that it has been eatly bisected to produce two volumes of equal size. Part I ntains London and the Provinces as far as most of the ay through S. One wonders what the arguments were gainst two volumes of unequal size, part I to contain London nd the whole of the Provinces. For ready reference one ill have to memorise either the name at the end of part I r that at the beginning of part II. All the usual helpful atures of this directory are still present.

ART IN MEDICINE

To achieve a faithful record of what he sees, the artist eeds a keen eye and unflagging self-discipline; for the atural impulse is to emphasise and interpret, thus clouding ctuality—for better or worse. This temptation has been hunned by Miss Anna Zinkeisen in most of her medical ictures, which are being exhibited at Foyle's bookshop in haring Cross Road. The exhibition, which remains open ill June 19, shows how ably Miss Zinkeisen has fulfilled her ask as artist to St. Mary's Hospital, Paddington. Whether howing the brave improvisation of the first-aid station, the ustle of the casualty department, or the surgical team at ork in the theatre, Miss Zinkeisen paints with restraint and cute observation. Despite good use of colour, these might ot be comfortable works to live with—the precision of detail nd the artist's personal unobtrusiveness make for a rather rittle coldness—but they should not be lost to the record. Less formal drawings of air-raid casualties are alive with the ictims' sense of bewilderment and shock; and, in lighter ein, some outpatient studies are good entertainment. The xhibition includes pathological drawings lent by the Royal ollege of Surgeons. These prove that, whatever the merits f photography, the artist retains a place in this field. The everal hospitals which are said to be toying with the idea of ppointing artists will find fresh impetus in Miss Zinkeisen's ork; but whether they will find artists with Miss Zinkeisen's are qualities is another matter.

"FAMILY"

As a topic, family life has never been exhausted; and a new magazine,[2] edited by Crystal Herbert in consultation with the Family Relations Group, confidently undertakes to talk of nothing else. The first issue, prefaced by the good wishes of Lord Horder, as chairman of the group, merely opens the windows on the limitless prospect. It tells of home life in a prefabricated house, of the management of adolescence (both by the sufferer and those about him), of home life in Russia, of education weeks when fathers can visit the schools of their children and see what goes on, of music for children, of keeping the doctor away, of the Coventry Health Club and their plan for a family colony, of broadcasting in the children's hour, and of Parliament and the family. There are also some good pages on household equipment, new books for parents and likely books for children, and a journal of the editor's own family living in a Kentish village. Plenty of line drawings and some pleasant photographs lead the reader on, to his profit.

DUTIES OF THE PRACTICAL NURSE

Some weeks ago we referred to an analysis[3] made in America of the duties of the practical nurse. It showed that this type of nurse—who corresponds in many ways to our assistant nurse—can relieve the fully trained nurse of a great number of duties which call for common sense, kindness, and good manners rather than great technical knowledge. We have since received a much more comprehensive analysis[4] of practical nursing, with suggestions for training programmes. This has been drawn up by a working committee made up of representatives of interested bodies in the fields of education, nursing, and the health services. The analysis is exceedingly detailed, covering 120 pages of the stout report; it represents the best American professional judgment on the duties which may be fittingly undertaken by practical nurses, and is recommended in the foreword as an authoritative source of information for the development of an acceptable curriculum.

Though American hospital conditions differ in many ways from ours, in all important respects they are similar, and a study of this analysis will interest all who have to plan training courses for either assistant or State-registered nurses. Besides showing how much a fully qualified nurse could safely leave to a properly trained assistant, it enumerates as practical nursing duties some tasks which are at present ignored in our hospitals or may be undertaken at random by the sister, nurse, student, or orderly, or in some instances by the ward-maid. These include such things as regulation of light, ward temperature, and ventilation, care of ward cleaning equipment and its use, care of refrigerators, care of hearing-aids, prostheses, and colostomy belts, and the arrangement of menus and preparation of various types of food—such as cooked and uncooked fruit, hot and cold drinks, fresh and frozen vegetables, salads, and salad dressings.

At the technical end of her scale of duties, the practical nurse is expected to be able to give various types of enema, to apply first aid, to look after the patient's mouth, bowels, fingernails and toenails, and corns and callouses, to apply poultices and insert suppositories, to take temperatures and examine urines, look after the incontinent patient, give baths, give injections, prepare special diets, feed infants, and apply bandages. Evidently the committee see the practical nurse as an all-round capable woman willing to do anything within her scope to make the patient comfortable.

It is interesting that the report, though it includes some thoughts on planning the curriculum, gives no outline of a theoretical course designed to accompany this practical training. Clearly the committee put practice a long way ahead of theory in the training of this type of nurse.

ALL ABOUT THE CANTEEN

The Industrial Welfare Society have published a 6th edition of their best-seller, *Canteens in Industry*.[1] This guide to planning, management, and service has proved its worth. Well illustrated, with plenty of facts and figures, it should supply all the information needed by firms setting up new canteens or determined to improve old ones. The facts given are based on the practical experience of canteen managers and others. Besides new plans of canteens of different sizes, the book contains much about premises, methods of service, finance, staff, food and diet, and legal aspects.

VITAMIN SUPPLEMENTS

The Ministry of Food now issues three vitamin preparations for children and expectant mothers in quantities which will provide the following supplements:

Preparation	*Issued to*	*Daily supplement*
Concentrated orange juice	Expectant mothers ..	Vitamin C 40 mg.
	Infants under 6 months	„ 13 mg.
	Children between 6 months and school age	„ 26 mg.
Cod-liver oil compound	Preschool children and expectant mothers	Vitamin A 4000 I.U. Vitamin D 700 I.U.
Chocolate-coated vitamin A and D tablets	Expectant mothers ..	Vitamin A 4000 I.U. Vitamin D 800 I.U. Calc. phosph. *B.P.* 250 mg. Pot. iodide 0·13 mg.

A charge of 5*d*. per bottle is made for the orange juice when the applicant can afford this; otherwise all the preparations are free. The Ministry's announcement in our advertisement columns gives further particulars.

Woman Health Minister

Miss Mabel Howard, the new minister of health for New Zealand, is the first woman to be appointed to the New Zealand cabinet.

Civic Honour for Dr. C. W. Buckley

On May 30 the freedom of the borough of Buxton was conferred on Dr. C. W. Buckley in recognition of his services to the town for more than 40 years. Dr. Buckley, who became physician to the Devonshire Royal Hospital in 1912, is an alderman of the borough.

University of Oxford

On July 26 the honorary degree of D.SC. will be conferred on Dr. A. E. Barclay.

Royal College of Physicians of London

On Tuesday and Thursday, July 15 and 17, Prof. P. C. P. Cloake will deliver the Humphry Davy Rolleston lectures at the college, Pall Mall East, S.W.1. He will speak on the Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic.

London Blood Transfusion Service

The headquarters of the Greater London Blood Transfusion Service are now at 10, Collingham Road, S.W.5 (Frobisher 6477).

Research Defence Society

On Tuesday, June 17, at 3.15 P.M., at 26, Portland Place, London, W.1, Prof. G. H. Wooldridge, F.R.C.V.S., will deliver the Stephen Paget lecture on What Animals Owe to Experimental Research.

Passano Foundation Award

On June 12 in Atlantic City this award for 1947 will be presented to Mr. Selman A. Waksman, microbiologist at the New Jersey Agricultural Experiment Station, by Mr. Robert S. Gill, president of the Williams & Wilkins Company and of the foundation. Mr. Waksman will afterwards give an address on Antibiotics and Tuberculosis—a Microbiological Approach.

Royal Medical Foundation of Epsom College

Henry Duncalfe annuities of £30 p.a. each for spinsters in need of help will shortly be awarded by the council. Candidates must be daughters of registered medical practitioners and must have attained the age of 50. Pensions for impecunious doctors or their widows, and scholarships for their sons, are also available from the funds of the foundation. Forms of application may be had from the secretary, Epsom College, Surrey.

Hospital for Sick Children, Great Ormond Street

Members of the consulting staff of the hospital will in future see outpatients only by appointment. Appointments, which should be made by the patient's own doctor, preferably in writing, may be made for any time between 9.30 A.M. and 12.30 P.M. except on Sundays. Patients who attend without an introduction from a doctor will be examined in the receiving-room and only when necessary referred to a consultant.

Society for Relief of Widows and Orphans of Medical Men

The annual general meeting of the society was held on May 21, with Dr. R. A. Young, the president, in the chair. The resignation of Dr. Blackett was received, and in appreciation of his services as secretary for over 40 years he was elected a vice-president. During 1946 £4950 was distributed to the 52 widows who are beneficiaries. The membership of the society is now 281, of whom 160 are life members and 121 are ordinary members. Further particulars may be had from the secretary, 11, Chandos Street, London, W.1.

Central Drugs Laboratory for India

Under the Drugs Act the Biochemical Standardisation Laboratory at 10, Chittaranjan Avenue, Calcutta, has been constituted as the Central Drugs Laboratory. Its functions will include: (1) the analysis of samples submitted by customs collectors and courts of law, and (2) the granting of certificates of registration for patent and proprietary medicines with undisclosed formulæ. The Drugs Act and rules came into force on April 1, except the provisions for the registration of patent and proprietary medicines, which are to take effect on April 1, 1948.

British Empire Leprosy Relief Association

Dr. Gordon Ryrie has been appointed medical secretary of the association in succession to Dr. Ernest Muir who has retired.

Dr. Ryrie, who graduated M.B. at the University of Edinburgh in 1926, joined the Colonial Medical Service in Malaya two years later. He was appointed superintendent of Sungei Buloh Leper Hospital in 1930, where he remained until the end of 1945. During the Japanese occupation Dr. Ryrie organised his settlement as a base for aiding our troops, guiding them in the jungle and sending food and medical supplies. In January, 1944, the Japs became suspicious, and they put him in prison, later sending him to a labour camp where he remained until the liberation. Immediately after VJ-day, though in poor health, he resumed his work at the Sungei Buloh Hospital until the autumn of 1945 when he returned to England.

Society for Endocrinology

The following officers of this society have been el chairman, Mr. A. S. Parkes, SC.D., F.R.S.; secretary, Mr. S. Folley, PH.D.; treasurer, Mr. C. W. Emmens, PH.D.; of the *Proceedings*, Prof. S. Zuckerman, F.R.S.; members committee, Dr. P. M. F. Bishop, Dr. C. H. Gray, Mr. P. Williams, Prof. F. G. Young, D.SC.

Return to Practice

The Central Medical War Committee announces that Harold Park, F.R.C.S., has resumed civilian practice 40, Wilbury Road, Hove, 3, Sussex.

Foreign Awards

The following decorations have been conferred on R.A.M.C. officers in recognition of distinguished services in the cause of the Allies:

UNITED STATES

Legion of Merit.—Major-General W. C. Hartgill, C.B., M.C., K.H.S. (commander); Brigadier D. B. McGrigor, O.B.E. (officer).

Bronze Star Medal.—Lieut.-Colonel A. J. King, Major H. G. McQuade.

BELGIUM

Croix de Guerre 1940 *with Palms.*—Captain R. L. Rees.

CZECHOSLOVAKIA

Order of the White Lion (*3rd Class*).—Major-General Sir Henry Tidy, K.B.E.

Medal for Merit (*1st Class*).—Lieut.-Colonel Henry Ross, C.I.E., I.M.S.

Appointments

BALL, MARGARET, M.B. Camb., M.R.C.P.: asst. physician, the Elizabeth Garrett Anderson Hospital, London.

BRASH, DAVID, M.B. Glasg., D.M.R.: radiologist, Bolton Royal Infirmary.

BURT, H. A., M.B. Camb., M.R.C.P.: director of department of physical medicine, University College Hospital, London.

BYARS, J. R., M.B. Aberd., D.P.H.: senior asst. county and school M.O., Leicestershire.

DAVIES, I. G., M.D. Lond., M.R.C.P., D.P.H.: M.O.H. and school M.O., Leeds.

DOYLE, W. J., M.B. N.U.I., D.P.H.: deputy county M.O.H., Devon.

GEOHEGAN, V. P., M.B. Leeds, D.P.H.: deputy M.O.H., Weston-super-Mare.

HEWITT, SELWYN, M.B. Durh., B.HY., D.P.H.: senior asst. county M.O. and school M.O., Herefordshire.

KATZ, JACOB, M.D. Bratislava, D.P.H.: deputy M.O.H., Accrington.

LOUIS, FRANCIS, M.B. Lond., F.R.C.S.: accident and orthopædic surgeon, Great Western Hospital, Swindon.

PURDIE, A. W., M.B. Glasg., F.R.F.P.S., M.R.C.O.G.: obstetrician, North Middlesex County Hospital, Edmonton.

ROSE, MURIEL, M.B. Lond., M.R.C.O.G.: obstetrician, Redhill County Hospital, Edgware.

SHAW, C. H., M.B. Lond.: asst. M.O.H., Rotherham.

THORBURN, A. L., M.D. Belf., D.P.H.: senior asst. M.O., East Riding, Yorks.

TURNEY, H. F., D.M. Oxfd, M.R.C.P.: physician i.c. department of physical medicine, Southend-on-Sea General Hospital.

London County Council Mental Health Service:

Asst. medical officers:

AMINOFF, JACK, M.R.C.S.: Friern Hospital, New Southgate.

ANNEAR, M. W., M.R.C.S.: Cane Hill Hospital, Coulsdon.

JONES, R. M., M.B. Camb.: Banstead Hospital, Sutton.

MAY, P. R. A., M.B. Camb.: Bexley Hospital, Bexley.

Royal Berkshire Hospital, Reading:

EVANS, W. G., M.B. Lond., D.M.R.T.: director of radiotherapy department.

HOOPER, A. N., M.B. Camb., F.R.C.S.: obstetrician and gynæcologist.

WILLIAMS, R. H. H., M.B. Camb., F.R.C.S.E.: aural surgeon.

Royal Victoria Infirmary, Newcastle-upon-Tyne:

BLACK, J. I. M., M.D. Durh., F.R.C.S.: asst. surgeon to throat, nose, and ear department.

BRUMWELL, JOHN, M.B. Durh., F.R.C.S.: surgeon.

DAVISON, GEORGE, M.D. Durh., M.R.C.P., D.C.H.: associate physician, children's department.

DEWAR, H. A., M.D. Durh., M.R.C.P.: asst. physician.

GREEN, C. A., M.D., PH.D. Edin., D.P.H.: clinical bacteriologist.

HOUSTON, B. D., M.B. Durh., D.M.R.: asst. radiologist.

HUNTER, WILLIAM, M.D. Durh., M.R.C.O.G.: associate surgeon, gynæcological department.

JONES, J. D. T., M.S. Durh., F.R.C.S.: asst. surgeon.

LAKE, L. H., M.B. Durh., D.O.M.S.: asst. surgeon, ophthalmic department.

MILLER, H. G., M.D. Durh., M.R.C.P., D.P.M.: asst. physician.

MILLER, J. F. W., M.D. Durh., M.R.C.P., D.C.H.: associate physician, children's department.

PASK, E. A., O.B.E., M.B. Camb., D.A.: head of department of anæsthetics.

RANKEN, MARGARET, M.B. Durh.: associate surgeon, ophthalmic department.

REID, J. L., B.M. Oxfd, D.L.O.: asst. surgeon, throat, nose, and ear department.

ROSE, J. D., M.B. Durh., F.R.C.S.: asst. surgeon.

STABLER, F. E., M.D. Durh., F.R.C.S., F.R.C.O.G.: asst. surgeon, gynæcological department.

WAY, S. A., M.R.C.S., M.R.C.O.G.: associate surgeon, gynæcological department.

WRIGHT, ELSIE, M.D. Lond.: associate physician, children's department.

THE CLINICIAN AND THE RH FACTOR*

Sir Leonard Parsons
M.D. Lond., F.R.C.P., F.R.C.O.G.
EMERITUS PROFESSOR OF PÆDIATRICS IN THE UNIVERSITY OF BIRMINGHAM

During the last five or six years research into the genetics and serology of the Rh factor has so completely monopolised the stage that there has been a tendency to overlook the important contributions which clinicians have made to our knowledge of the disorders due to it. Moreover, even when their work is acknowledged, little credit is given to British pædiatricians. Thus, in his lecture to this faculty on "The significance of the Rh factor in medicine and obstetrics," in 1944, Prof. D. F. Cappell did not give a single reference to the work of a British clinician. The present lecture is therefore, in great part, a plea for the recognition of the work of British pædiatricians, particularly that of some of my colleagues. My thesis is that the conception and proof that "erythroblastosis" is a hæmolytic disease was chiefly the work of the Birmingham school of pædiatrics; a fact which has been generously recognised by Professor Cappell (1946) in his most recent papers. The actual factor causing the hæmolysis—the Rh antibody—was demonstrated by American workers in a series of brilliant observations, and the demonstration of the various subgroups of the Rh factor and the explanation of seeming inconsistencies in its action have been the work of British and American serologists.

HISTORY OF HÆMOLYTIC DISEASE

In view of my claim for the Birmingham school of pædiatrics it is not without interest that the first description of icterus gravis was in a report published in 1902 on "A family series of fatal and dangerous cases of icterus neonatorum—fourteen cases in one family with four survivors," by Dr. J. A. Arkwright, who practised at Halesowen within five miles of the Children's Hospital, Birmingham. A description of another "Series of cases of jaundice in the fœtus" was published in the same year, but in 1905 a contribution appeared which was even more interesting than Arkwright's paper, since it was written by Dr. G. A. Auden, who later became physician in charge of the psychiatric department of the Birmingham Children's Hospital. This paper bore the title "A series of fatal cases of jaundice in the newborn occurring in successive pregnancies," and the description of the clinical characteristics of the condition is so accurate that it might have been written yesterday. He summed them up as follows:

(1) The appearance of the disease in successive children of the same parents.

(2) The rapid development within a few hours of birth of a jaundice which quickly became profound.

(3) The occurrence of a generally drowsy condition which usually ended in convulsions, terminating fatally.

(4) The severe anæmia, which became more and more marked as the colour of the jaundice waned, and which persisted for a lengthy period in those affected children who survived.

(5) The "hepatogenous" characteristics of the jaundice and absence of any form of hæmorrhage.

He even thought it probable that a stillborn child and two abortions in the same family were due to the same cause which produced the jaundice in the children born alive. This remarkable little paper is indeed a veritable clinical cameo. A paper by Dienst, of historical interest, was also published in 1905 in which he stated that "eclampsia is nothing but a transfusion of incompatible blood of the child into the mother's circulation as a result of a communication between the two," and suggested that the same process might take place in the child if the mother's blood gained access to it.

Pfannenstiel first used the term icterus gravis in 1908, and a year later Buchan and Comrie described extramedullary hæmopoiesis in association with it, a combination to which in 1912 Rautmann gave the name of erythroblastosis. There was no further paper of importance until 1920, when the late Sir Humphry Rolleston, who thought that the disease was due to "fœtal toxæmia of maternal origin," reviewed 130 cases of "grave familial jaundice of the newly born" with a case-mortality of 77%. In 1923 Ottenberg, recalling Dienst's paper on eclampsia, said that it seemed possible that jaundice of the newborn "may be due to the same cause, accidental placental transfusion of incompatible blood," but produced no evidence in support of his theory.

Six years later Hampson propounded a view which was a complete reversal of this theory. He thought that the hæmolysis which, since red blood-cells are not immortal, constantly occurs in intra- and extra-uterine life was kept in check during fœtal life by something produced by the mother and passed on to the fœtus, and after birth produced by the baby. This "something" limited the hæmolysis at birth to the production of physiological jaundice; but, if it were absent or diminished before or after birth, hæmolysis proceeded unchecked, producing severe jaundice and anæmia. Further, he maintained that this hæmolysis could be prevented by the injection of blood-serum into the baby because, whereas before the adoption of this treatment 75 out of 90 cases in the families of his patients died, after its adoption 17 out of 18 recovered. In the same year Goldbloom and Gottlieb showed that the hæmolysis at birth, which always produced bilirubinæmia and sometimes also physiological jaundice, was due to the postnatal readjustment from an environment which required polycythæmia for adequate oxygenation to one in which polycythæmia was not necessary.

Stimulated by Hampson's work and by the researches on nutritional anæmia of Elvejhem in America and Helen Mackay in England, we began in 1930 investigations into the anæmias of infancy and childhood which are still in progress, and in 1933 I was able to write as follows:

> "Sometimes in the newborn child hæmolysis is severe and unchecked and a profound anæmia of the hæmolytic type develops within a few days of birth. This form of hæmolysis occurs in familial icterus gravis. As a result the bone-marrow is stimulated and the extramedullary centres of the erythron recalled into activity, and a form of erythroblastosis of the newborn is produced."

Two years previously Burnham and Sanford in America had again put forward the view that the grave familial jaundice of newborn infants was due to the persistence of a phenomenon of fœtal life—erythroblastosis—and in 1932 this theory was elaborated by Diamond, Blackfan, and Baty, of the Boston school, with the result that icterus gravis became widely known as erythroblastosis.

The next important advance in our knowledge was the almost simultaneous demonstration by workers in Boston and in Birmingham that hydrops fœtalis, icterus gravis, and hæmolytic anæmia of the newborn were different manifestations of the same underlying condition. The Boston school believed that this underlying condition was a primary erythroblastosis, whereas my colleagues and I (1933) were convinced that the primary factor in the disease was hæmolysis and that the erythroblastosis was a compensatory mechanism, being in fact an attempt, by reverting to a fœtal type of erythropoiesis, to elaborate more red cells to take the place of those destroyed. Moreover, we maintained that the agent which destroyed the red cells often also affected the hæmopoietic centres—i.e., the whole of the erythron—and that the resulting

---

* A lecture delivered before the Royal Faculty of Physicians and [illegible] 19, 1947.

recovery stages; moreover it may be found in other conditions, such as syphilis and sepsis, or even in the ormal full-time baby at birth. Syphilis and sepsis may fact present every clinical and hæmatological sign icterus gravis, even indeed kernicterus.

PROGNOSIS

Death is the inevitable outcome of hydrops, whereas fter appropriate treatment complete recovery usually ccurs in hæmolytic anæmia of the newborn, except on hese extremely rare occasions when after the acute hase a hypoblastic anæmia develops which may last any months. In icterus gravis recovery may now be xpected in about 70% of patients, but some of these, ariously estimated at 5–15%, will develop severe cerebral ymptoms, and a smaller proportion cirrhosis of the liver. t is usually impossible to say in any given case of icterus ravis that cerebral symptoms will develop; this is nfortunate because, were it possible, it would surely e justifiable to withhold treatment in the hope that the hild would die. Rarely in those babies who have ernicterus there is rigidity and even opisthotonos, and should be afraid that a baby who had convulsions would ater show cerebral symptoms. I also think a high-itched cry suggests kernicterus. Rigidity may be first oticed at the age of six months, especially if the baby as an intercurrent infection.

PATHOGENESIS

At one time we thought that biliary obstruction by viscid bile produced by a rapid hæmolysis was the cause of the guinea-gold obstructive type of jaundice seen in icterus gravis, which differed so much in appearance from the lemon tint usually seen in hæmolytic anæmia, though it seemed obvious that sometimes also another factor was present which produced the necrosis of the liver which we found at necropsy. We did not pay sufficient attention to the fact that in hæmolytic anæmia of the newborn there was only a minimal amount of jaundice, though the degree of hæmolysis was much greater than in icterus gravis. We now know that, though mechanical obstruction may play a small part, the jaundice is in the main due to the pathological action of the Rh antibodies on the liver cells. Wiener (1946a) maintains that the liver damage is due to the plugging of the smaller arterioles by agglutination thrombi produced by the combination of maternal Rh agglutinins (bivalent antibodies) with the Rh-positive red cells of the fœtus. He also holds that the plugging of terminal vessels in the brain produces ischæmic infarcts and kernicterus, and that a similar process in the marrow acts as an irritant to the marrow and causes erythroblastæmia. Whether Wiener's views or ours are correct, two facts in addition to necrosis of the liver cells show that the injury to these cells is the primary cause of the jaundice: (1) my colleagues Dr. A. R. Meyer and Dr. E. M. Hickmans (1945) have shown that the cholesterol partition in the liver in icterus gravis is abnormal; and (2) biliary cirrhosis sometimes appears as a late sequel to icterus gravis in exactly the same way as it occurs at times after an attack of infective hepatitis. Henderson (1942) has reported biliary cirrhosis in macerated fœtuses the subjects of icterus gravis, but we have only occasionally found an increase in reticulin fibres, and the appearance within the lobules of fibres staining with van Gieson's stain, in children who have died before the 8th day, though cirrhotic changes have not been uncommon in children dying at a later stage.

The staining of the nuclear masses in the brain in association with neonatal jaundice was first described by Orth in 1875 and called kernicterus by Schmorl in 1904. These cerebral changes are thought by some observers to be due to fixation of antibody in the nerve-cells similar to the process which I have described in the liver, but probably neither this nor ischæmic infarction is the correct explanation. In our view the changes are the result of liver damage—a hepatic encephalopathy not unlike that which occurs in progressive lenticular degeneration, though there is probably no connexion between the Rh factor and Wilson's disease. The evidence in favour of our theory is as follows:

(1) After careful search my colleague Dr. Baar has never found occlusion of blood-vessels by agglutination thrombi in kernicterus, though hyaline thrombi such as occur in a variety of diseases have been found occasionally.

(2) We have observed kernicterus in two jaundiced babies in whom iso-immunisation by the Rh factor was excluded by serological tests.

(3) The occurrence of miliary necrosis in the liver in an infant associated with histological changes in the brain similar to those in kernicterus but without any bile staining (Baar 1946).

In our view the sequence of events in kernicterus is an antigen-antibody reaction between the liver cells and the Rh antibody, resulting in necrosis of the liver cells, which is followed by necrosis of the brain cells, and these necrosed cells then become stained by the bile pigment. Kernicterus,. therefore, is not due to hæmolysis, and we have never found any parallelism between, on the one hand, the degree of hæmolysis and, on the other, the severity of the jaundice and the presence of kernicterus.

In this connexion, the differing manifestations of hæmolytic disease of the newborn in what were apparently identical twin boys are interesting. Since at birth their weights were almost equal it is reasonable to suppose they received an equal share of antibodies, yet one was more severely jaundiced but less anæmic than the other, had a mild degree of kernicterus, and when his incisor teeth erupted the enamel was coloured green, whereas his brother had neither of these conditions. Staining of the temporary teeth, usually the incisors, is one of the rare sequels of icterus gravis, its incidence being considerably less than that of biliary cirrhosis. There is no evidence of the premature death of the enamel cells, and the condition is probably linked with the severity of the jaundice, comparable with extensive staining of the bones by bile which I have seen in a severe case of icterus gravis.

Wiener states that plugging of the vessels in the liver and brain does not occur in hæmolytic anæmia of the newborn or in hydrops fœtalis, but that the changes in those conditions are due to blocking antibodies or glutinins. Thus, if the maternal serum contains these blocking antibodies in small amounts, the child is either born anæmic or develops anæmia shortly after birth; but, when larger quantities are present, the process progresses further in utero until the anæmia is so severe that œdema develops through anoxæmia of the capillary wall (hydrops).

Now, as we have seen, he has said that erythroblastæmia is caused by agglutination thrombi in the smaller arterioles in the bone-marrow which have been formed by the action of bivalent antibodies on the red cells; yet erythroblastæmia may occur in the normal newborn baby and is often present in hæmolytic anæmia of the newborn in which, according to him, this plugging of vessels does not take place.

Though his explanation of erythroblastæmia therefore appears illogical, Wiener's theories are of considerable importance in explaining certain diagnostic tests and because of the treatment based on them. He assumes that the bivalent agglutinins combine with the antigens on the surface of the red cell and form a lattice, each agglutinin binding two cells together, and therefore clumping occurs in any medium, saline or serum. Blocking antibodies or glutinins are presumed to be smaller and therefore able to traverse the placenta more readily than bivalent antibodies and to be univalent, since they

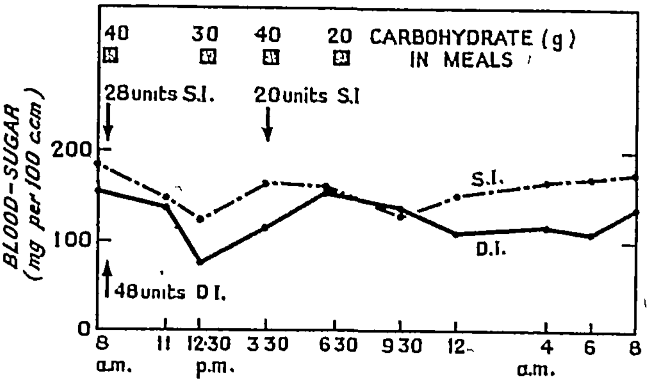

Fig. 3—Blood-sugar responses to a single dose of D.I. 48 units and to two doses of S.I. (28 and 20 units) in case 1.

Case 2.—A man, aged 44 years, weight 9 st. 7 lb., diabetic for 16 years. S.I. 24 units twice daily covered diet of carbohydrate 140 g., protein 80 g., and fat 100 g. Fasting blood-sugar 88–143 mg. per 100 c.cm.; urinary sugar 0–6 g. in 24 hours. Single dose of D.I. 48 units before breakfast for 4 weeks gave a variable response; fasting blood-sugar 180–268 mg. per 100 c.cm.; urinary sugar 7–35 g. in 24 hours. Returned to S.I.

The remaining 6 patients, who were given single doses of D.I. ranging from 50 to 108 units, all showed consistently a similar type of response. The blood-sugar level fell to reach hypoglycæmic levels 3–8 hours after the injection. Despite lunch and tea, low or normal levels were maintained until about the 11th hour, when supper was given. Thereafter, in all but 2 patients, a progressive hyperglycæmia ensued, to give a high fasting value next morning (fig. 4). In 2 patients the insulin action was sufficiently prolonged to deal with the carbohydrate at supper, and seemed to last for 16 hours (fig. 5, single-dose curve).

It is thus obvious that D.I., in single doses of 50 units or more, acts too strongly 3–8 hours after injection, often cannot deal with the carbohydrate at supper (11 hours after injection), and cannot prevent nocturnal hyperglycæmia.

Subsequently, in 4 of these patients and in 1 other who was not tried on a single dose, we divided the dose of D.I., giving 50–75% before breakfast and the remainder before supper. The blood-sugar was estimated 24-hourly for 2–3 days. The effect was satisfactory in 4 cases as regards the 24-hour excretion of sugar and the absence of hypoglycæmia; but the blood-sugar, though well controlled during the day and part of the night, rose in the hours before breakfast (fig. 5, two-dose curve). An attempt to obtain a fasting blood-sugar of 100–200 mg. per 100 c.cm. by giving a sufficiently large evening dose caused hypoglycæmia during the night, despite extra carbohydrate given at 10 P.M. Case 3 illustrates the improved control obtained by dividing the large dose of D.I.

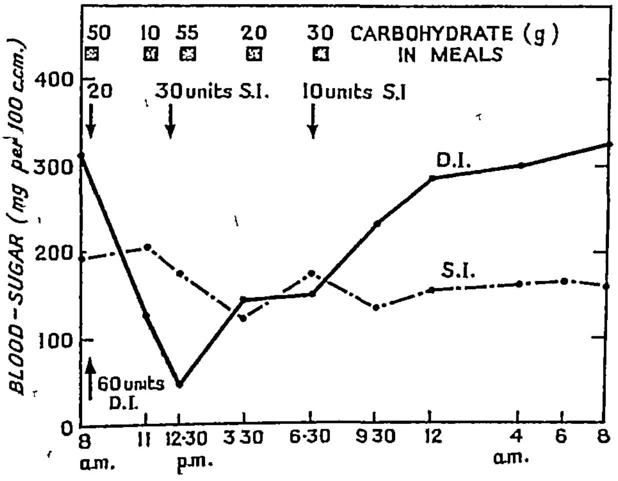

Fig. 4—Blood-sugar responses to repeated injections of S.I. and to a single injection of D.I. Note hypoglycæmia at 12.30 p.m. and lack of control from 6.30 p.m. onwards. Urinary sugar on S.I., 0·5 g. daily; on D.I., 12–21 g. daily.

Case 3.—A man, aged 65 years, weight 9 st. 2 lb., diabetic for 4 years. Diet: carbohydrate 140 g., protein 90 g., and fat 100 g. Three doses of S.I. (20, 10, and 20 units) gave fasting blood-sugar levels of 182–234 mg. per 100 c.cm.; urinary sugar 3–8 g. in 24 hours.

On a single dose of D.I. 50 units before breakfast: fasting blood-sugar 250–324 mg. per 100 c.cm.; urinary sugar 10–21 g. in 24 hours; hypoglycæmia between lunch and tea.

On two doses of D.I., 36 units before breakfast and 20 units before supper: fasting blood-sugar 193–290 mg. per 100 c.cm.; urinary sugar 1–6 g. in 24 hours (fig. 5).

In the patient who did not do well on D.I., each dose of 50 units (before breakfast and tea) acted well for 6 hours but was spent by 8 hours. On substituting S.I. for D.I. a similar duration of action was obtained.

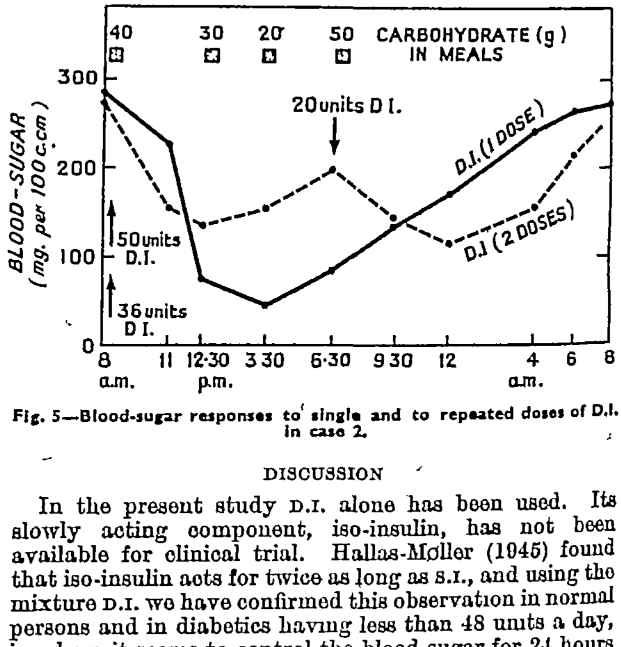

Fig. 5—Blood-sugar responses to single and to repeated doses of D.I. in case 2.

DISCUSSION

In the present study D.I. alone has been used. Its slowly acting component, iso-insulin, has not been available for clinical trial. Hallas-Møller (1945) found that iso-insulin acts for twice as long as S.I., and using the mixture D.I. we have confirmed this observation in normal persons and in diabetics having less than 48 units a day, in whom it seems to control the blood-sugar for 24 hours (fig. 3). But with doses of D.I. larger than 48 units the prolonged action of the iso-insulin component is not always seen (fig. 4). Indeed in some instances the duration of action of D.I. seems to be little greater than that of S.I. Of 7 patients having 50 units or more, in 2 only did the effect last for 16 hours; in the others, 8–12 hours.

This unexpectedly short action of D.I. in large doses is often, though not always, associated with symptoms of hypoglycæmia 3–8 hours after injection. Possibly the compensatory glycogenolysis plus the carbohydrate of the later meals may produce a hyperglycæmia which cannot be dealt with by the iso-insulin component. This may explain most cases where the long action of iso-insulin is not evident; and it indicates, we think, a fault in the D.I. mixture—i.e., that the S.I. content is too high. In some patients, however, who had neither clinical nor biochemical hypoglycæmia with large doses, the duration of action was still much less than was expected. In his experiments on rabbits Hallas-Møller (1945) found certain animals which showed a S.I.-like effect when given iso-insulin, but in depancreatised dogs and in human diabetics iso-insulin showed only a protracted effect, save in some cases, when hypoglycæmia was induced; the reactionary hyperglycæmia then masked the prolonged action of iso-insulin. *This requires further* lucidation, since some of his results and some of ours ould be interpreted as showing that iso-insulin sometimes as a S.I.-like effect.

As stated above, the proportion of S.I. in D.I. seems nnecessarily high. Since iso-insulin is acting strongly hours after injection, only sufficient S.I. need be present n the mixture to deal with the hyperglycæmia following reakfast. This would diminish the tendency of D.I. to nduce hypoglycæmia 3–8 hours after injection. MacBryde and Roberts (1943) have found 25% S.I. activity in a Z.P.I.-S.I. mixture to be adequate; and, in a short linical trial of a similar mixture which had 23% rapid ction, we obtained satisfactory control of the blood-ugar during the early part of the day in the 4 diabetics who were given the mixture (unpublished work). The difficulty of having such mixtures prepared commercially in this country precluded a more extensive trial.

It thus seems clear that D.I. in its present form is not a satisfactory single-injection preparation for severe diabetes. Single doses of 50 units or more act too strongly 3–8 hours after injection, and too feebly thereafter. These defects may be partly overcome, as Hey (1945) has shown, by dividing the total requirements into two doses. Even with this scheme, in our experience, there is a risk of hypoglycæmia during the night, if the evening dose is sufficiently large to give a satisfactory blood-sugar level before breakfast.

No local or general reactions (save hypoglycæmia) have occurred from D.I. in our patients who have been on D.I. for 2–6 months. At present 6 patients are doing well: 4 are having single doses of 12, 20, 20, and 48 units; the others two daily doses, 40 and 30, followed by 36 and 20 units.

SUMMARY

The effect of di-insulin, which consists of equal parts of soluble insulin and a slowly acting derivative, phenyl-ureido-insulin (iso-insulin), has been tested in 5 normal persons and 12 diabetics.

The protracted effect of the iso-insulin component was demonstrable in the normals and in diabetics requiring less than 50 units of insulin. In the latter a single injection of di-insulin controlled the blood-sugar throughout the 24 hours; but in those requiring 50 units or more one injection of di-insulin was unsatisfactory, producing hypoglycæmia 3–8 hours after injection, and not controlling the blood-sugar in the late evening and during the night. Possible explanations for this are discussed.

The soluble-insulin content in the di-insulin mixture is thought to be too high.

We are greatly indebted to the subjects, both normal and diabetic, who willingly submitted to the frequent blood sampling; to Sisters McNeill, Davidson, Pyper, Ross, and Watson for their coöperation: to Mr. A. McCutcheon for technical assistance; and to the late Prof. Noah Morris for his stimulation and guidance. Our thanks are also due to Novo Terapeutisk Laboratorium, Copenhagen, for ample supplies of di-insulin, which were made available to us through Mr. C. L. Bencard, of London, and Mr. S. Home, of the Corporation Central Drug Store, Glasgow; and to Mr. W. A. Broom, of Boots Pure Drug Co., Ltd., who in 1943 supplied us with special batches of Z.P.I. and S.I., which when mixed gave a known excess of S.I. Part of the expense of this investigation was met by a grant from the Medical Research Council.

TYPING OF TYPHOID BACILLI WITH Vi BACTERIOPHAGE

SUGGESTIONS FOR ITS STANDARDISATION

JAMES CRAIGIE
O.B.E., M.B., Ph.D. St. And., F.R.S.C., F.R.S., D.P.H.
RESEARCH MEMBER, CONNAUGHT MEDICAL RESEARCH LABORATORIES, UNIVERSITY OF TORONTO *

A. FELIX
D.Sc., F.R.S.
DIRECTOR, CENTRAL ENTERIC REFERENCE LABORATORY, PUBLIC HEALTH LABORATORY SERVICE (MEDICAL RESEARCH COUNCIL), LONDON

IN 1938 Craigie and Yen reported that different types of *Salmonella typhi* could be identified by means of certain specific Vi-phage preparations. They concluded that the types were stable, and suggested that the phage-typing method might be of value as an epidemiological tool. Subsequent experience has established the value of this method beyond any doubt (for references see Felix 1944, Buckle 1946). So far 24 types or subtypes of *S. typhi* have been identified. The method of Vi-phage typing has been extended by Felix and Callow (1943) to *S. paratyphi B* and *S. typhi-murium*.

The phage-typing method reveals strain differences which cannot be demonstrated by any serological method. Because these strain differences remain unaltered on human passage and, with certain exceptions, on subculture in the laboratory, they provide a means of identification whereby transmission in man may be traced. A carrier may be absolved from responsibility for a given outbreak if he is excreting a strain of *S. typhi* which differs in Vi-phage type from those isolated from the cases. The phage-typing method permits the epidemiologist to trace the connexions between sporadic cases of typhoid, a task that cannot be accomplished without this new laboratory technique. The typing of carrier strains and the recording of carriers and of the Vi-type which each excretes are of obvious value. In all its aspects the phage-typing method conserves time, effort, and expense in epidemiological investigation and the tracing of sources of infection. In the experience of one of us (A. F.) during seven years this method was an indispensable aid to the control of typhoid fever.

Though the practical value of the phage-typing method has been established, all its possibilities have not yet been explored. Any typing scheme recommended at present must be designed to accommodate new types that may be found later in different parts of the world. In this era of quick transport typhoid patients and carriers are constantly moving from one country to another, establishing new foci of infection. Because of the adaptability of the agent used for typing, serious confusion may arise if supposed new types or subtypes are added without complete characterisation of phage preparations prepared locally and used for routine typing purposes.

Obviously provision will have to be made by an authoritative international body, so that reference standards, both cultures of Vi-type strains of *S. typhi* and standard typing-phage preparations, should be available to all using the method. Preparations of Vi-phage II have been preserved in a fluid state for over eight years without detectable alteration or deterioration in activity. This stability provides a potent argument in favour of the adoption of Vi-phage preparations as the ultimate standards of reference. Observations on many strains of *S. typhi*, maintained for years on the best medium available—i.e., Dorset egg medium—have shown that strains of some types may become sensitive to heterologous phage preparations. Examples of this loss of specificity are referred to below. It is clear that preparations of Vi-phage II, not cultures of the type-strains of *S. typhi*, should be selected as the basic reference materials to achieve standardisation of typhoid phage-typing over a maximum of time. Meanwhile a typing scheme is suggested to ensure uniformity of technique and to enable workers in different parts of the world to exchange cultures and phage preparations.†

---

* Now a member of the staff of the Imperial Cancer Research Fund, London.

Some aspects of the phage host-cell relationships are of great theoretical interest, but they are far from being completely understood at present. In view of the well-established value of phage-typing, the design and acceptance of a working scheme permitting full use of the method cannot be deferred until the various mechanisms involved have been clarified. Since the practical value of the method lies in its epidemiological application, a scheme for practical use must be based on practical, not theoretical, considerations. The purpose of the method is to determine whether or not any two or more cases of typhoid infection are derived from a common source. Obviously, differences in phage susceptibility which do not represent stable characteristics cannot be accepted for the purposes of a practical epidemiological scheme, though they may be of academic interest. The scheme must be so designed, on the basis of existing knowledge, that the user can interpret type similarities or dissimilarities without hesitation. In other words, a scheme which is to be used as an epidemiological guide must be based primarily on epidemiological evidence.

The epidemiological information which has been accumulated in various countries to date has been carefully considered before proposing the present scheme and making the recommendations which follow. This scheme will have to be extended as new types or subtypes are discovered. The test for the validity of the scheme or any part thereof is its conformity with epidemiological data. Final acceptance of the types and subtypes of the scheme, or of any new types that may be added, must rest on epidemiological evidence.

All the phage preparations used for the identification of the types and subtypes listed in the proposed scheme have been derived from one strain of specific typhoid Vi bacteriophage—i.e., the Vi-phage II (strain 6) described by Craigie and Yen in 1937 and 1938. Though the same scheme might result from the use of another strain of serologically similar adapted Vi-phage, this cannot be assumed a priori. Until extensive comparative investigations have been made, the routine typing of strains of *S. typhi* should be carried out exclusively with the preparations of Vi-phage II giving the reactions specified in the scheme. All these preparations have been subjected to neutralisation tests with serum prepared from the original Vi-phage II, and all were serologically identical.

Even the use for routine purposes of typing preparations made independently by propagation of the type phages received from us should be avoided because of the known risk of accidental contamination of the original Vi-phage II with other strains of bacteriophage. Such an accident may result from airborne contamination in a laboratory where other phage preparations are being handled, or by propagation of Vi-phage II on phage-carrying strains of *S. typhi* that have not been recognised as such. There is also the danger that propagation of Vi-phage II on cultures of certain Vi-types *may lead to* a permanent change in the characteristics and affinity of the phage. For these reasons, new batches of Vi-phage II preparations should be subjected to appropriate tests before being employed in routine typing. Any new lot of phage preparation must meet the minimal requirement that it will produce the reactions specified in the scheme summarised in table II. More extensive tests, based on certain cross-reactions obtained with concentrations of phage greater than the routine test concentration, are necessary if a phage preparation is to be completely defined or a change in differential activity is to be detected. Further, as a safeguard against unsuspected contamination with another bacteriophage, it is recommended that every new preparation of Vi-phage II should be neutralised with specific antiserum

NOTES ON INDIVIDUAL TYPES

The following types and subtypes merit special comment:

Type A.—This occupies an exceptional position in the phage-typing scheme in that it is fully sensitive to all Vi-phage II preparations. Epidemiological observations on numerous groups of cases and related carriers infected with such strains appear to warrant the retention of Type A in the scheme. However, laboratory observations extending over seven years suggest that Type A should be regarded as an infrequent variant of some of the other Vi-types of *S. typhi.*

Type A has been isolated from cultures of strains of Types B_1, C, D_1, F_1, N, O, and T (Craigie 1940, Felix unpublished observations). *Most of these observations have been made on* strains maintained in the laboratory a long time, though occasionally the appearance of Type A has also been noted shortly after isolation.

Of even greater importance, from the point of view of the epidemiologist, is evidence that such a dissociation may occur in chronic carriers of long standing. In one instance

CL = Confluent lysis. – = No plaques. ± = A few plaques usually present. +, 2 +, 3 + = Increasingly numerous plaques. n = Normal plaques. s = Small plaques, visible to the naked eye. m = Minute plaques, visible only by means of magnifying lens (×10).

Type A was isolated from a primary plating from a Type O carrier, and in another instance from a Type T carrier. Possibly environmental changes involved in transfer of the organisms to laboratory media may have provided the necessary conditions for the emergence of Type A.

These facts must, therefore, be borne in mind when an infection with Type A is encountered in apparent association with infections due to one of the other types. A single source of infection cannot be absolutely excluded when one of the types concerned is Type A.

Some strains of other Vi-phage types have become less specific after prolonged subculture, a few plaques of subnormal size being obtained with the routine test dilution of all or some of the heterologous phage preparations. This may possibly be a partial change in the direction of acquisition of Type A characteristics, but the phenomenon requires further investigation.

Type B_1.—The merging of Types A and B_1 in the temporary simplified scheme suggested by Craigie (1942) was based on the view that B_1 might be a variant of Type A, standing in the same relationship to Type A as E_2 does to E_1, or F_2 to F_1. Since, as mentioned before, Type A has appeared on several occasions in cultures of other types, it seems better for practical purposes to retain Type B_1 as an independent subtype of the B group.

Type D_3.—In view of the evidence now available, subtype D_3 is regarded as a degraded strain of Type N and is therefore withdrawn from the scheme. The original D_3 type-strain was isolated in 1938 at Chatham, England, and was classified as one of the D subtypes because it showed cross-reactions only with phage D_1 and phage D_2 (Craigie 1941).

More recently, discrepant results in London and Toronto led to the discovery that cross-reactions of this strain depend, to a remarkable extent, on temperature and medium. As observed by one of us (J. C.), the Chatham strain is resistant to all heterologous phages if tested on 'Difco'-broth agar at a temperature exceeding 38°C, but cross-reactions are well marked between 33°C and 37°C. Moreover, the addition of certain supplements to the medium alters this critical temperature. Cross-reactions are suppressed in the presence of dextrose, but are greatly enhanced by the addition of 5% glycerol with 0·05% phenol to the medium.

Type D_5.—So far only one strain of this type has been encountered, and it is uncertain whether the patient had been infected in Britain, India, or elsewhere (Felix 1943). Type D_5 gives very strong cross-reactions with all phage preparations for Type D_4. This unusually marked cross-reaction requires further investigation. It may be due to the fact that the available cultures of D_5 have undergone degradation since the strain was isolated in 1942.

Types F_1 and F_2.—The isolation of subtypes F_1 and F_2 by Helmer et al. (1940) from the same patient indicates that they are closely related, and that their differentiation may not be of epidemiological significance. However, further observations on this point are desirable.

Type K.—This is the former subtype B_4. It was originally allocated to the B group because the cultures exhibited well-marked cross-reactions. A recent study of the original B_4 type-strain on Difco-broth agar confirms that it is a specific independent type.

On tryptic-digest agar, however, this strain now gives numerous cross-reactions, whereas less than a year ago it gave the specific reactions shown in table II. This change cannot be attributed solely to differences in medium, because in recent tests on tryptic-digest agar, carried out with the original B_4 type-strain and another B_4 strain isolated in 1943 in England, the latter strain gives the specific Type K reactions previously obtained with the old B_4 strain, which now gives many cross-reactions.

Type N.—Phage preparations for Type N (hitherto known in England as Type Richmond) and the Chatham strain (formerly called subtype D_3) are indistinguishable. Type N strains, however, differ considerably in their resistance to heterologous preparations of Vi-phage II. Some are sensitive only to phage N; others, like the Chatham strain, may show well-marked cross-reactions.

Since phage N and phage D_3 are similar, the strains of *S. typhi* producing these phages must be regarded as essentially similar.

The reasons for the differences in resistance of Type N strains to heterologous preparations are unknown. The loss of specificity does not appear to be a progressive change solely related to long subculture. A few Type N strains reacted with most of the heterologous phages immediately after isolation from the patients, whereas strains isolated in other localities gave a pure Type N reaction and maintained this characteristic almost indefinitely on subculture.

Type O.—This type, which had been provisionally labelled Type 91 (Felix 1943), is common in Britain and has been encountered in many countries.

Some strains of Type O develop plaques of normal size, and with these strains complete lysis is readily obtained with the homologous phage after incubation for about eight hours. At the same time single plaques may also develop with the test dilutions of several other type phages, similar to the readings on a Type C strain.

On the other hand, many Type O strains support only minute plaques, which can be seen only when the plates are inspected with a magnifying lens and strong transmitted light. This peculiarity is not due to degradation, since strains freshly isolated by blood-culture from very severe or fatal cases may yield minute plaques, whereas other strains which have been maintained in the laboratory for several years still develop large plaques.

Strains yielding minute plaques with Type O phage usually do not give any overlapping reaction with any of the other type phages. It is therefore essential to take a first reading after incubation for about eight hours at 38°C, and another after incubation for twenty-four hours.

According to conditions depending on the composition of the agar medium the minute plaques may sometimes be overgrown and ill-defined after incubation for twenty-four hours. In other instances a doubtful result obtained at the first reading may change into a clear-cut positive result after further incubation.

Type T.—This was referred to in a previous paper (Felix 1944) under the letter T. It has not been considered desirable to alter this designation, though letters P, Q, R, and S remain unallocated.

UNTYPABLE Vi STRAINS

About 5% of strains of *S. typhi* encountered in Great Britain cannot be typed. Such untypable strains fall into two groups: (1) strains resistant to existing phage preparations; and (2) strains exhibiting anomalous and partial sensitivity to several phage preparations.

(1) It now seems desirable to use the term "untypable Vi strain" in preference to the original term "imperfect V form," which was applied to phage-resistant strains. Such strains may include Vi-phage types to which Vi-phage II has not yet been adapted.

Countries in which phage typing has not been used may be expected to provide, initially, a higher ratio of untypable strains in proportion to the presence of hitherto unknown types.

In attempts to adapt Vi-phage II to resistant strains, phage preparations of the B and D groups should not be used until repeated tests have shown that adaptation cannot be accomplished with a concentrated preparation of the standard phage A or, if this fails, with repeated attempts with all the other standard phage preparations.

It appears desirable that further new types which, undoubtedly, will be encountered in various parts of the world should receive some temporary form of designation other than that used in the scheme given in table II. Extension and modification of this scheme and the incorporation of new types are obviously a matter for consideration by some international body.

Some untypable Vi strains carry a potential lytic agent or bacteriophage, termed "gamma agent" by Craigie (1942). The resistance of these strains to Vi-phage II appears to be a phenomenon analogous to the interference effect known to occur between certain plant or mammalian viruses.

(2) Reference has already been made to strains which acquire a decreased specificity after prolonged subculture. Strains may be encountered which behave in a similar way on initial test, yielding plaques of subnormal size with all or some of the available series of Vi-phage preparations.

The method of indirect phage typing may be of value in the further investigation of such strains, provided that Vi-phage II can be adapted to them. Phage so obtained is tested, in its critical test concentration for Type A, on all the known Vi-types of *S. typhi* and on the homologous strain.

MATERIALS AND METHODS

The method of typing typhoid bacilli with Vi bacteriophage has been described in previous publications (Craigie and Yen 1938, Craigie 1941). On the basis of practical experience of the method of one of us (A. F.) during seven years it is recommended, for the routine typing of strains, that the details of the technique originally described be followed as closely as possible. The points that require comment here are those which, in the light of experience and special studies, appear to be of especial importance in connexion with standardisation.

Agar Medium for Typing.—It must be borne in mind that one essential prerequisite, on which the lytic activity and multiplication of Vi-phage II depends completely, is active metabolism of Vi antigen by the culture of *S. typhi* to which the phage is added.

The number and size of plaques obtained with homologous and heterologous phage preparations vary from type to type, and each type exhibits a characteristic pattern of susceptibility (table II).

Extraneous factors, such as medium and temperature, influence the extent of plaque development and may affect the specificity of the reactions obtained with some of the types and subtypes. The former Type D_3, for example, yields highly specific reactions under some conditions and exhibits well-marked cross-reactions under others. It is therefore obvious that the composition of the medium used for typing is of the greatest importance in any attempt at standardisation of the typing technique.

The ideal to be aimed at is a synthetic standard medium, but this is not likely to be realised in the near future. A satisfactory and readily prepared medium, devised and extensively used by one of us (J. C.), has the following composition:

'Bacto' nutrient broth (dehydrated) ‡ ..	20 0 g.
Sodium chloride	7·5 g.
'Bacto' agar	20·0 g.
Distilled water to	1000 ml.

The final hydrogen-ion concentration of this medium is about pH 6·8 and should not be adjusted with alkali.

Alternatively, any good tryptic meat-digest agar may be used, provided that the phage reactions stated in table II are reproduced in every detail. Each batch of agar medium should be compared with the previous batch by testing the type-strains N, O, and T against the whole series of typing phages. If the agar medium permits of full development of the small-size plaques that characterise these Vi-phage types the batch can be accepted for use in routine typing. Papain agar has been found unsatisfactory and should not be used.

The tryptic meat-digest should be made from 500 g. of fresh meat to 1000 ml. of water. Neutralisation with excessive amounts of NaOH must be avoided; otherwise the alkaline change which accompanies growth of *S. typhi* may be accelerated and exaggerated.

Excessive amounts of phosphate tend to inhibit lysis, and care should be taken to precipitate and remove these so far as possible. The final hydrogen-ion concentration of the trypsin-digest agar should be about pH 7·4.

The cultures are first grown in Difco broth or trypsin-digest broth to which has been added 1% peptone. After two or three hours' incubation at 38°C the broth cultures have usually grown sufficiently to be transferred to agar plates, which should contain a fairly thick layer of agar medium, about 25–30 ml. per Petri dish of 9 cm. diameter.

Occasionally a strain belonging to any one of the various Vi-phage types may be encountered which consistently yields dwarf colonies on Difco agar or trypsin-digest agar. These strains cannot be typed on plain agar, but normal growth and susceptibility to Vi-phage II are restored by the addition of 0·2% sodium thiosulphate to the medium (Kauffmann 1935, Wilson 1938).

The addition of certain substances to the medium may much influence plaque development. Glycerol, for example, as originally shown by Desranleau (personal communication) significantly enhances plaque size. The mechanisms whereby various supplements affect plaque size are obscure, but the subject merits further study with a view to the ultimate development of a standard medium.

Temperature of Incubation.—The lower temperature limit to the lytic activity of Vi-phage II is about 33°C. This does not mean, however, that a considerable departure from 37°C in plate temperature can be tolerated. It is recommended that a minimal temperature of 37–38°C should be maintained throughout the whole period of incubation, because lower temperatures tend to favour the development of cross-reactions.

Interrupted incubation of phage tests, as originally suggested by Craigie and Yen (1938), may be chosen to suit laboratory routine, but continuous incubation, with readings at eight hours and twenty-four hours, appears to be preferable.

Reading of Tests.—Phage tests should be read against a dark background with suitable oblique lighting. All areas which appear doubtful or negative to the naked eye should be inspected with a × 7 to × 10 hand lens.

Some of the later Vi-types of *S. typhi* now included in the typing scheme yield only minute plaques or micro-plaques with homologous phage. Micro-plaques are also found in certain cross-reactions. Plaques of subnormal size are sometimes encountered in atypical strains belonging to those Vi-phage types that usually yield plaques of normal size. Since the routine test concentrations of the phage preparations are adjusted for the development of plaques of normal size, such atypical strains will show only imperfect clearing in the area covered by homologous phage.

---

‡ Beef extract and peptone mixture supplied by Difco Laboratories, Detroit, Mich., U.S.A.

In an extreme case, where interpretation is doubtful, it will be necessary to resort to indirect typing by growing Vi-phage II on the strain and testing the phage preparations on cultures of the reference type-strains.

Preservation and Maintenance of Type Cultures.—There is ample evidence that environmental conditions prevailing during long-term preservation of strains of *S. typhi* may influence their degree of susceptibility to Vi-phage II. Reference has been made to the appearance of Type A in cultures of strains belonging to different Vi-phage types, and to a change in the direction of decreased specificity on the part of others.

The relationship of such variations to medium used for the maintenance of stock cultures requires long-term study. Some strains may have a greater inherent capacity to vary than other strains. It is also possible that undesirable variants may selectively grow and survive in the presence of certain metabolites or at certain final hydrogen-ion concentrations which do not necessarily bear any relationship to that of the uninoculated medium.

Meanwhile it is recommended that cultures of the Vi-type strains be maintained on Dorset egg medium, being stored in a dark and cool place, preferably at 4°C, after a minimum of incubation at 37–38°C.

Fresh stock cultures should always be prepared from the oldest viable stock culture available. The following procedure has proved to be satisfactory: transfer from old Dorset egg slant to fresh Dorset egg slant and incubate overnight; plate on agar plate and incubate overnight; select about a dozen of the best-looking opaque smooth colonies and seed together on slants of Dorset egg medium for storage.

Preservation by special procedures, such as drying, is to be avoided for the time being.

Preservation of Phage Preparations.—Concentrated fluid preparations of Vi-phage II, if free from living bacteria, retain their potency unaltered for years at 4°C. The high dilutions used for typing also keep well, at least for several months, but it is desirable to keep the volume of these to a convenient minimum, replacing them at intervals from suitable intermediate concentrations.

VI-PHAGE TYPING OF OTHER MEMBERS OF THE SALMONELLA GROUP

The arrangement of types and subtypes of *S. paratyphi B* in the typing scheme suggested by Felix and Callow (1943) has also been based on the principles recommended here. The same applies to a typing scheme of *S. typhi-murium*, devised by Felix and Callow but not yet published, which has been used in the epidemiological investigation of outbreaks of food-poisoning in Britain during the past few years. For the sake of uniformity it is highly desirable that the same procedure should be followed in any future attempt at phage typing of *S. paratyphi A* or other member of the salmonella family.

Our thanks are due to Miss B. R. Callow, of London, and Miss E. M. Clark, of Toronto, for their help in preparing and testing some of the bacteriophages and in maintaining the cultures.

FOLIC ACID IN AGRANULOCYTOSIS

D. A. K. BLACK
M.D. St. And., M.R.C.P.
LECTURER IN MEDICINE

S. W. STANBURY
M.B. Manc.
CHIEF ASSISTANT

DEPARTMENT OF MEDICINE, ROYAL INFIRMARY, MANCHESTER

It has been known for some time that folic acid is effective in correcting nutritional cytopenia in monkeys (Wilson et al. 1942): and the granulopenia produced in rats by sulphonamides can also be prevented by folic acid. In human beings, Menten and Graff (1946) found that sulphonamide granulopenia gave no very definite response to pyridoxine and folic acid, but their daily dosage of folic acid was less than 0·2 mg. Watson et al. (1945) reported improvement in irradiation leucopenia with folic acid.

In the two cases of agranulocytosis reported below the granulocytes returned to the blood-stream within forty-eight hours of giving adequate doses of folic acid.

Case 1.—A woman, aged 51, was admitted to a surgical ward on Jan. 18, 1947, for operative treatment of toxic goitre.

A month earlier she had had a sore throat and skin rash following barbiturate medication; no blood-count had been done and she had recovered after the barbiturate had been stopped.

On Jan. 18 she was given gr. $1^1/_2$ of 'Dial.' Next day she became severely ill, with fever and sore throat. A blood-count on the 20th confirmed the diagnosis of agranulocytosis—white cells 1600 per c.mm. (0·5% polymorphs).

Treatment with penicillin 30,000 units three-hourly and 'Pentnucleotide' 40 ml. daily was begun on the 20th; and on the 21st she began to have pyridoxine 200 mg. daily. She remained febrile, and her blood-count did not improve.

On the 24th treatment with folic acid 20 mg. daily was started. Within forty-eight hours her temperature had fallen to normal, granulocytes had returned to the blood-stream, and she was clinically much better.

A marrow smear done by Dr. H. Lempert on the 21st had shown a striking lack of granulocytes. On the 27th granulocytes, from the promyelocyte stage to fully mature polymorphs, had reappeared in the marrow.

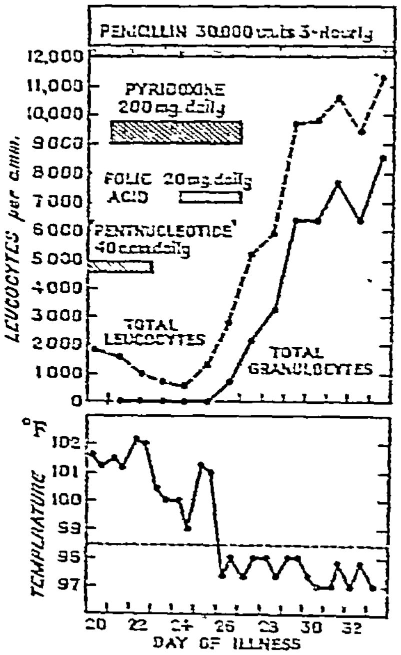

Fig. 1—Treatment, temperature, and white-cell counts in case 1.

The time-relations of treatment and improvement in the temperature and blood-count are shown in fig. 1.

Case 2.—A woman, aged 53, was admitted to hospital on April 5, 1947, with a history that, three weeks earlier, she had developed a vague febrile illness diagnosed as influenza. Convalescence had been slow, and on March 23 she had become acutely ill, with sore throat, headache, and fever.

On this and several subsequent days she had been given an amidopyrine hypnotic for control of headache (she had also had amidopyrine in 1945 for migrainous headache).

A throat swab had been negative, and she had been given penicillin 200,000 units b.d. for four days. She had remained ill and febrile, and on April 1 she had been given penicillin again, 400,000 units b.d.

A blood smear taken on March 31 had been reported as suggesting leucopenia, with lymphocytes predominating, and retrospective inquiry showed that no polymorphs were seen. A firm diagnosis of agranulocytosis was not, however, made until April 5, when her total white cells numbered 900 per c.mm.

After admission to hospital on April 5 treatment was with penicillin 62,500 units three-hourly; intravenous pyridoxine 300 mg. within the first twenty-four hours and folic acid 100 mg. followed by 20 mg. daily.

Within forty-eight hours her temperature had settled and granulocytes had returned to the blood-stream.

A bone-marrow smear, taken ten to twelve hours after the start of therapy, showed maturation arrest at the promyelocyte level; no mature granulocytes were seen. A further marrow smear, taken just over twenty-four hours later, showed granulocyte development along normal lines.

Fig. 2 shows the time-relation between treatment and improvement.

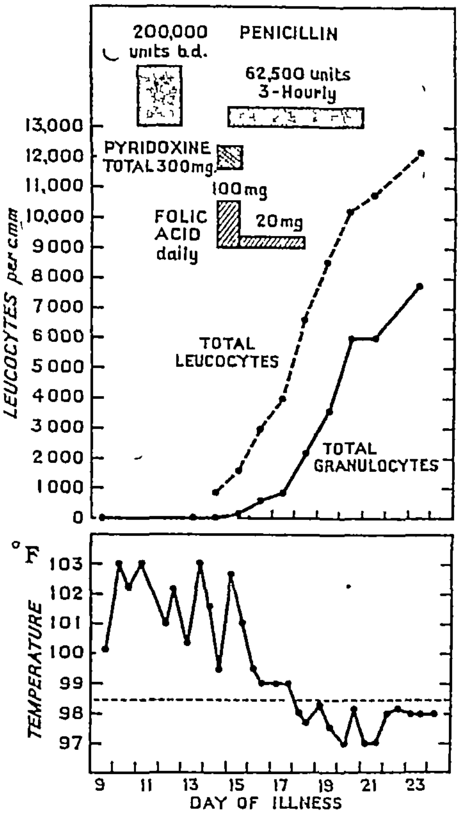

Fig. 2—Treatment, temperature, and white-cell counts in case 2.

COMMENTS

These two cases illustrate the value of penicillin in maintaining life during the period of agranulocytosis. Pyrexia, however, continues despite penicillin and does not settle until polymorphs reappear in the circulating blood. There is, no a-priori reason to suspect that penicillin has any stimulant action on leucopoiesis, and in both patients granulocytes had not returned after five days' penicillin therapy. Apart from penicillin, the only drug other than folic acid given to both patients was pyridoxine; in the first patient pyridoxine had been given, without response, for three days before folic acid was added. We realise that spontaneous remission may occur at any time in this disease, and that the appearance of granulocytes within forty-eight hours of giving folic acid to these two patients may have been merely a coincidence. We propose to treat subsequent patients with folic acid and penicillin alone; but, since agranulocytosis is comparatively rare, others may have an opportunity of testing the value of folic acid before another case is available to us.

We are indebted to Messrs. Lederle, Inc., New York, for supply of 'Folvite.'

TRAUMATIC NEURITIS OF THE DEEP PALMAR BRANCH OF THE ULNAR NERVE

W. RITCHIE RUSSELL
M.D. Edin., F.R.C.P.

C. W. M. WHITTY
B.M. Oxfd, M.R.C.P.

From the Department of Neurology, Radcliffe Infirmary, Oxford

THE correct diagnosis of the cause of wasting of the muscles of the hand is clearly a matter of practical importance, and in this connexion Russell Brain et al. (1947) have recently clarified the causes of median neuritis. We draw attention here to another cause of wasting of the hand which is in our experience specially liable to faulty diagnosis.

Traumatic, occupational, or pressure neuritis of the ulnar nerve is a relatively common cause of such wasting. In most cases the neural injury occurs either at the elbow or at the wrist, and injury at these sites can be distinguished by studying the muscles paralysed and the extent of the sensory loss.

Injury to the deep palmar branch of the ulnar nerve may, however, provide a clinical picture quite unlike that generally associated with ulnar paralysis. When it occurs without any obvious injury to the hand, the nature of the lesion is apt to be overlooked by the clinician, and indeed there is a danger that motor-neurone disease may be diagnosed.

Anatomy.—The anatomy of the nerve in the palm is given in Cunningham's (1937) textbook as follows:

> "The ulnar nerve in the hand divides under cover of the palmaris brevis muscle into its two terminal branches—superficial and deep. The deep palmar branch is almost purely motor. It passes deeply between the flexor and abductor minimi digiti; it supplies these muscles and the opponens digiti minimi, then turning laterally along the line of the deep palmar arch, and under cover of the deep flexor tendons, it supplies branches to the following muscles: interossei, third and fourth lumbricals, the adductor pollicis, and the deep part of flexor pollicis brevis."

This is its usual anatomy, but it should be borne in mind that there may be variations. The nerve occasionally supplies opponens and abductor pollicis brevis; flexor pollicis rarely has an entirely median supply (Highet 1943); and the first two palmar interossei are sometimes innervated by the median (Pollock 1919). This may cause some difficulty in interpreting the clinical signs of injury.

When the deep palmar branch is injured at its origin without involvement of the superficial branch, the muscles supplied by the ulnar nerve are paralysed without sensory loss. Hunt (1914) quotes six cases observed by him in which this occurred. When, however, the deep palmar nerve is injured after its branches to the hypothenar muscles have been given off, and while running laterally with the deep palmar arch, the interossei and adductor pollicis are paralysed but the hypothenar muscles are unaffected. This isolated muscular paralysis without sensory loss constitutes the essential clinical feature of the cases here recorded.

Case 1.—An R.A.S.C. sergeant, aged 24, reported weakness of the right hand, with difficulty in writing, which had been present for about 15 days. Some 3 weeks previously he had ridden a motor-cycle with a defective *twist-grip throttle* from Algiers to Sousse, at times over rough and difficult roads. For 24 hours after completion of this journey he had noticed paræsthesia in the little and ring fingers of the right hand. This had cleared spontaneously. During the ensuing 3 weeks he had been employed on routine short motor-cycle journeys. He had noted the weakness when trying to write a letter about a week after his long journey. It appeared to be increasing.

On examination he appeared a healthy rather thick-set man. The only abnormality in the central nervous system was weakness and slight wasting in the interossei and adductor pollicis of the right hand; the hypothenar muscles were ntact, and there was no objective sensory loss.

He was put off cycling duties and told to rest the hand as much as possible. He was seen again some 3 months later. He had only stayed off cycling for about 3 weeks, by which time he thought his hand so much better that he resumed full duty. He now had no disability and no detectable weakness, though there was still a slight reduction in the muscle mass of the first interosseus space.

Case 2.—A Pioneer Corps private, aged 32, reported weakness of the left hand for about 1 month. He dated the symptoms from a time when he had been preparing the site for a tented camp. For about a week his chief occupation had been putting tent-pegs into clay soil, pushing them in by hand and then hammering them home. Since then he had been employed on digging.

On examination he had evident wasting of first interosseus and adductor pollicis, and weakness of all interossei, third and fourth lumbricals, and adductor and flexor pollicis brevis of the left hand. There was no involvement of the hypothenar muscles and no sensory loss.

He was put on light duty and instructed to rest the hand as much as possible. He did not report again, but his medical officer stated 6 weeks later that he had made no further complaints.

Case 3.—A retired civil engineer, aged 61, complained of weakness of the right hand and difficulty in holding a pen for writing for about 2 months. One evening after a heavy day's gardening he had noticed painless swelling of the right hand. This had subsided gradually in a few days, and he had begun to note the weakness which had remained stationary since then. His gardening activities at the time of onset had consisted of breaking up hard clods of earth with a spade, which he held in his right hand and crashed down on the earth.

On examination there was weakness, with some wasting, of all interossei, third and fourth lumbricals, and adductor pollicis of the right hand. The hypothenar muscles were normal, and there was no sensory loss. No other abnormality.

He was advised to rest his hand and to wear a thick glove to prevent trauma to the palm. A follow-up 4 months later showed improvement in the weakness and wasting. The patient, who was an accurate observer, gave a good description of the recovery he noted. At first full power returned to the little finger (the disability here had been of adduction due to interosseus weakness); next it returned to the middle and index fingers; and improvement in thumb movements was slowest. Difficulty in holding a pen for writing had decreased considerably.

Case 4.—A pressed-steel worker, aged 33, complained of weakness of the left hand for 6 weeks, with wasting for about 2 weeks. For the past 2 months his work had involved straightening dents in various pieces of pressed steel. For this he had rested a block of wood on the palm of his left hand, while with his right hand he hammered the dent out against the block.

On examination there was marked weakness of all interossei, third and fourth lumbricals, and adductor pollicis, with obvious wasting of first interosseus and adductor pollicis. The hypothenar muscles were unaffected, and there was no subjective or objective sensory disturbance.

He was advised to change his work. When seen again 7 weeks later there was much improvement in weakness and wasting. He no longer noted any subjective disability, and had changed his job to that of milk roundsman.

Case 5.—An insurance agent, aged 48, reported weakness of the right hand and difficulty in writing, of gradual onset, over the past 3 months. He had a Dupuytren's contracture of the palm which had been slowly increasing for years but had not interfered with his work. During the past 3 months he had noticed a gradually increasing weakness of the right hand, showing itself particularly in difficulty in holding a pen for writing. There had also been some wasting of the hand.

On examination a Dupuytren's contracture could be felt and seen centred mainly over the flexor tendons of the fourth finger. There was evident wasting of the interossei and adductor pollicis, and weakness of interossei, third and fourth lumbricals, adductor and flexor pollicis brevis. The hypothenar muscles were not involved, and there was no subjective or objective sensory loss.

In view of a possible constriction of the nerve by fibrous tissue, surgical exploration was undertaken by Prof. H. J. Seddon. However, no mechanical obstruction was found to a seeker passed across the palm in the course of the nerve. Electrical stimulation gave a normal response in branches to the hypothenar muscles, but none beyond this. Electromyograms from the muscles affected showed no evidence of fibrillation.

DISCUSSION

There are few published reports of this traumatic or pressure palsy of the deep palmar branch. Ramsay Hunt (1914) does not describe this particular condition, but Harris (1929) gives details of two such cases, one in a bootmaker and one in a cyclist. In the further cases here described, the connexion between trauma to the palm of the hand and the onset of the paralysis was quite definite, but it must be emphasised that careful inquiry is often needed to elicit the cause of the injury, as the patient is usually unaware that he has damaged his hand in any way.

The deep palmar branch of the nerve, after turning laterally in the hand, lies in close relation to the proximal end of the metacarpal bones, and these no doubt provide a hard surface against which the nerve can be compressed.

The obvious treatment, which consists in avoiding the causes of trauma, is usually successful in allowing recovery to occur spontaneously.

SUMMARY

Pressure on the deep palmar branch of the ulnar nerve may cause a neuritis. Various occupations can inflict trauma of this kind.

The result is paralysis and wasting of the interossei and adductor pollicis muscles. There is no sensory loss, and the hypothenar muscles may be unaffected.

Recovery usually follows discontinuance of trauma to the hand.

A CASE OF HICCUP

REVIVAL OF AN OLD REMEDY

R. C. NAIRN
M.B. Lpool
LATE SURGEON LIEUTENANT R.N.V.R.

THIS case is recorded mainly because of the treatment adopted, but the ætiology is also worthy of discussion.

During operational minesweeping off Malaya a request was received from another ship for medical attention for a naval stoker who had had hiccup for forty-eight hours. Treatment was prescribed, to be carried out in the rating's ship till he could be transferred. He did not respond to the remedies suggested—all old and well-tried methods, such as breath-holding, breathing in and out of a paper bag, traction on the tongue, and eating or drinking such things as sugar and eucalyptus oil (we had no cajuput) or sugar and vinegar.

He was transferred for treatment on the same evening, Sept. 6, when he was found to be truly suffering from hiccup of an unbelievable forcefulness. He had vomited twice during the day, and this was not surprising, from the mechanical effect of his spasms alone. He had diarrhœa on this day only. There were no other symptoms, no domestic or other worries, and no relevant past illnesses. He gave a history of a normal pulmogram earlier in the year. His wife had had a pleural effusion but was recovering rapidly, and he was not concerned about her. The patient was 30 years old.

On examination he was well built, reasonably cheerful in spite of having been hiccupping for the past two and a half days, and looked very fit. There was violent frequent hiccup, with a periodicity of about 30 sec. (This was later noted to persist while he slept.) No pyrexia, pulse normal, tongue clean and moist. No abnormal abdominal, respiratory, or cardiac signs; blood-pressure normal.

Central nervous system (C.N.S.): slight nystagmus, maximal on looking to the right; right knee-jerk absent, left sluggish; slight but definite unsteadiness of gait but no true rombergism.

The clinical picture was ascribed at the time to some organic lesion of the C.N.S. yet to be determined; meanwhile treatment was directed to stopping the hiccup.

Treatment.—A mixture of oxygen and 7% carbon dioxide was administered with a 'Novox' apparatus for long periods, but without effect. Phenobarbitone gr. 3 statim and gr. 2 b.i.d. was given to allay his growing anxiety. He was put to bed. An hour later he was still hiccupping as badly as ever. *Mist. kaolin et morph.* (*N.W.F.*) $^1/_2$ oz. was given to relieve any possible gastric irritation, and he fell asleep, still hiccupping.

He stopped hiccupping in the early hours of the morning, much to everyone's relief, and on waking remained free from hiccup until he drank a little fluid about half an hour later. This started him off again. (Solid food was withheld until there was no doubt about his complete recovery.) Hyoscine hydrobromide gr. $^1/_{75}$ was then given by mouth to reduce parasympathetic activity, and he was put on an antacid powder, again directed against possible gastric irritation.

In the afternoon of this day the patient was still hiccupping and had become a little less cheerful. Again the novox apparatus was tried, this time for periods of 15 minutes, alternating with 15-minute periods of abdominal compression produced by flexing his thighs (Hutchison and Sherren 1925). This was given up after an hour as being too exhausting in the heat of the afternoon and singularly ineffective. Various "tricks" were then resorted to, such as holding down the cricoid cartilage, and traction on his tongue—without effect.

The only treatments left seemed to be the administration of a general anæsthetic, either ether or 'Pentothal' (the only ones available), and, if that failed, phrenic-nerve paralysis either by procaine injection or avulsion. Before seriously contemplating these heroic procedures, a mental survey was made of the drugs supplied to small ships. One antispasmodic, amyl nitrite, was available, and this had not yet been tried.

Inhalation of the vapour from one ampoule of amyl nitrite worked like a charm, and in less than a minute his hiccup had stopped. A slight recurrence three hours later was treated in the same way, and this time he remained quite free from hiccup.

Progress.—Next day he was allowed some semi-solids by mouth, but he complained that the food stuck at the level of the lower end of his sternum. On re-examination his C.N.S. signs were unchanged, apart from the addition of slight intention tremor. Œsophageal spasm was diagnosed and attributed to the same general C.N.S. lesion which had caused the hiccup. A mixture of belladonna, kaolin, and morphine was given for the next week to assist his swallowing.

On Sept. 10 he was free from symptoms, though the signs were unchanged, and he was regarded as fit for light duty until he could be transferred to hospital for a complete neurological investigation. He was seen regularly until Oct. 27, when he was discharged to the Royal Naval Auxiliary Hospital, St. Peter's, Colombo. The physical signs had become less pronounced but were still qualitatively unchanged on Oct. 23. In St. Peter's a full investigation was made, but by this time he was practically clear of abnormal physical signs and was quite symptomless. Apart from sluggish tendon jerks and an absent lower left abdominal reflex, nothing of importance was recorded. His optic disks were normal and visual fields full; a slight choroiditis was regarded as being inactive and not significant. There was no abnormality in the cerebrospinal fluid (C.S.F.): the Kahn test was negative, as was the blood Kahn. Nothing abnormal was discovered in the urine. A barium swallow revealed no œsophageal or periœsophageal lesion.

DISCUSSION

Diagnosis.—It is unfortunate that hospital investigations could not be undertaken before the clinical condition had cleared. The diagnosis remains uncertain. Bellingham Smith (1938) gives the following differential diagnosis:

(1) Hiccup due to peripheral nervous causes—irritation of either the phrenic or vagus nerves.

(2) Hiccup due to central nervous causes: brain tumour; meningitis; hydrocephalus; encephalitis lethargica (either epidemic or sporadic, with or without other symptoms and signs); epilepsy; hysteria; toxæmia (e.g., of specific infections, metabolic disorders, and uræmia); reflex causes.

Besides these causes, on theoretical grounds at least, such central nervous lesions as neurosyphilis and disseminated sclerosis should also be included.

In the present case peripheral lesions were excluded by the presence of C.N.S. signs, and the short duration and recovery ruled out brain tumour and hydrocephalus. The absence of meningism ruled out meningitis. There was no evidence of epilepsy. Reflex causes and hysteria were ruled out by the positive signs of organic nervous disease and the continuance of the hiccup during sleep. There was no evidence of toxæmia. Negative Kahn blood-test and C.S.F. findings excluded neurosyphilis. The remaining possibilities appear to be sporadic epidemic encephalitis (for no other cases occurred in the area) and disseminated sclerosis. French and Douthwaite (1945) state that such sporadic cases of encephalitis do occur, and occasionally without pyrexia, with a normal C.S.F., and with little if anything to distinguish them from neurosis or hysteria, unless there have been other similar cases in the neighbourhood about the same time. In the present case other signs of central nervous disease were present, all compatible with such a diagnosis. Against a diagnosis of disseminated sclerosis is the fact that "intractable" hiccup appears never to have heralded an attack of this disease before. An attack of encephalitis lethargica, with the principal lesion in the medulla, is proposed as the most likely diagnosis in this case.

Treatment.—At the time I could find no record of amyl nitrite having been used in hiccup before, and I tried it on purely theoretical grounds. Since then, however, I have found that its use is mentioned by Osler (1942), Comrie (1937), and Bellingham Smith (1938). I have since employed it in a few other cases of hiccup, including alcoholic hiccup, with unequivocal success.

SUMMARY

A case of hiccup of nearly four days' duration and of doubtful ætiology is described.

The most likely cause seems to be encephalitis lethargica.

Inhalation of amyl nitrite was used with immediate success after most of the better recognised methods of treatment had proved unsuccessful.

Acknowledgments are due to the Medical Director-General of the Navy and the Medical Officer-in-Charge, R.N.A.H., St. Peter's, Colombo, for permission to publish this case.

". . . Here, then, is an affirmative answer to the question: Do we have the natural resources to meet world food goals by 1960? This answer is a challenge to all men, not to scientists only, for it raises immediately an even more critical question: Can we mobilize these resources to produce the needed food? This question begs many answers, because it involves the whole field of human relationships. Science may discover and point the way, but it cannot dictate. The full measure of success in economic, social, and political action comes only with the will of the majority—not from the desires of one group. If the people of the world really have the determination to give battle to the problem of hunger, if they are willing to expend a small part of the energy and capital poured into World War II, only then can we see hope of victory."—ROBERT M. SALTER, chief of the Bureau of Plant Industry, Soils, and Agricultural Engineering, U.S. Department of Agriculture, Beltsville, Maryland, *Science*, May 23, p. 533.

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

A MEETING of this association was held at Exeter, April 25 and 26, under the presidency of Mr. GEORGE RKINS.

Tuberculosis of Bones and Joints

Mr. G. R. GIRDLESTONE spoke of the rarity of dissemina- on of tuberculous infection by operation on bones and nts provided this was well timed and preceded and lowed by immobilisation. He condemned concern th the local lesion to the exclusion of the tuberculous tient as a whole, and emphasised the importance of ng-continued care after discharge from hospital. He garded serial estimations of the erythrocyte-sedimenta- on rate as valuable in assessing progress.

Mr. NORMAN CAPENER reviewed tuberculous disease the *spine* in 351 cases, laying stress on the difference the disease, and its response to treatment, in children d adults. In the first fifteen years lower thoracic orsal) disease predominated; afterwards, lumbar. 7 cases were treated by arthrodesis, with no mortality the first nine months; the tibia providing the graft actured but once, in contrast with the experience in aumatic cases. He thought the key to the treatment thoracic spinal disease might be treatment of the scess.

Mr. M. C. WILKINSON, speaking on tuberculous sease of the *hip*, had found an unstable joint in 22 out 50 cases treated conservatively alone. The value of peration was measured by its success in securing ability and in preventing recurrence. His operative mortality in 75 cases was: early 2, late 2. He had articularly practised osteotomy, with medial displacement of the distal fragment, but lately he had supplemented this by an extra-articular femoral graft slid long the upper border of the neck. Operation was erformed in the presence of active disease after the atient's resistance had been raised by conservative reatment; and the reossification which ensued might e ascribed perhaps to auto-inoculation or to the decompression of tuberculous foci. Bony ankylosis might ake as long as two years, though the hip usually became quite stable before this. Many radiograms were shown f patients so treated.

Mr. Wilkinson's view that displacement osteotomy was often of great value in the treatment of tuberculous hip-joints was supported by Mr. D. WAINWRIGHT, who showed how a combination of osteotomy and ischiofemoral graft produced rapid bony ankylosis; and he showed also the result of supplementing long oblique osteotomy by traction, so that not only was apparent lengthening produced by angulation but also real lengthening by distraction. Dr. J. DELCHEF advocated early arthrodesis while the disease was still active. Mr. H. A. BRITTAIN held that the hip demanded different treatment from the other joints of the lower limb, because it could be short-circuited from weight-bearing by ischiofemoral arthrodesis.

Mr. J. P. CAMPBELL reviewed 89 cases of tuberculosis of the *knee* treated at Harlow Wood Orthopædic Hospital and found a quarter of them purely synovial. Some with osseous lesions developed a serviceable range of movement. Intra-articular arthrodesis resulted in bony fusion much more quickly in those of more than three years' standing than in more recent cases similarly treated. Bone-grafting operations were reserved for adults, in whom they supplemented intra-articular arthrodesis or were used to promote bony fusion where resection of the joint alone had failed.

Dr. J. MORTENS, reviewing 76 cases, concluded that arthrodesis should be postponed to the age of thirteen or fourteen if an epiphysis was involved, but that otherwise nine was not too early an age for the operation.

In considering 118 cases of tuberculosis of the *foot and ankle*, Mr. B. L. MCFARLAND contrasted the very good, though slow, response in children to conservative treatment with the frequently poor result in adults in whom dissemination or sinus formation often led to amputation. Conservative treatment, with or without arthrodesis, might be indicated in some younger adults, but in the older patient with tuberculosis of ankle or tarsus amputation was not merely justifiable but often imperative.

Mr. J. A. CHOLMELEY reviewed 94 of 100 cases of tuberculosis of bones and joints of the *upper limb* treated in the Royal National Orthopædic Hospital (country branch) in the years 1924–46. The parts affected were: shoulder (36 cases), elbow (25), wrist (22), metacarpals and phalanges (10), and humeral shaft alone (1). All received conservative treatment, supplemented in a few by operation—namely, arthrodesis of 8 shoulders in adults; excision of an elbow, and partial excision of another with drainage for secondary infection; local excision of the local humeral lesion. Arthrodesis of the shoulder—often determined by occupation—gave good results in adults, with bony fusion in every case, whereas recurrence took place in 3 of the shoulders not operated on. Two elbows, including that excised, showed recurrence. There was none in the wrist, metacarpal, phalangeal, or humeral cases.

Sir REGINALD WATSON-JONES concluded that tuberculosis of bones and joints presented, from the viewpoint of treatment, two diseases—that in children and that in adults. Both demanded conservative treatment; in children this sufficed, but in adults it should often be supplemented by surgical fusion after quiescence of the disease. The position was reversed in the case of the spine, which should be arthrodesed more often in children and more rarely in adults, because in children conservative treatment of dorsal disease left an unstable spine with increasing deformity, whereas in adults lumbar disease nearly always led to spontaneous ankylosis.

Cup Arthroplasty of the Hip

Dr. M. N. SMITH-PETERSEN (Boston, Mass.), who was elected an honorary fellow of the association, described his operation of cup arthroplasty. The restoration of shapely, smooth, cartilaginous articular surfaces was demonstrated by slides and films.

Mr. W. ALEXANDER LAW had found that some 80% of Smith-Petersen's cup arthroplasty operations gave a result satisfying to patient and surgeon; but the former must coöperate actively with exercises for two years.

Communications and Cases

Mr. H. G. S. KORVIN concluded, from radiological evidence, that the pathological changes in *pseudocoxalgia* are those of ordinary aseptic necrosis, and that destructive changes are the biological consequences of the mechanical damage of weight-bearing.

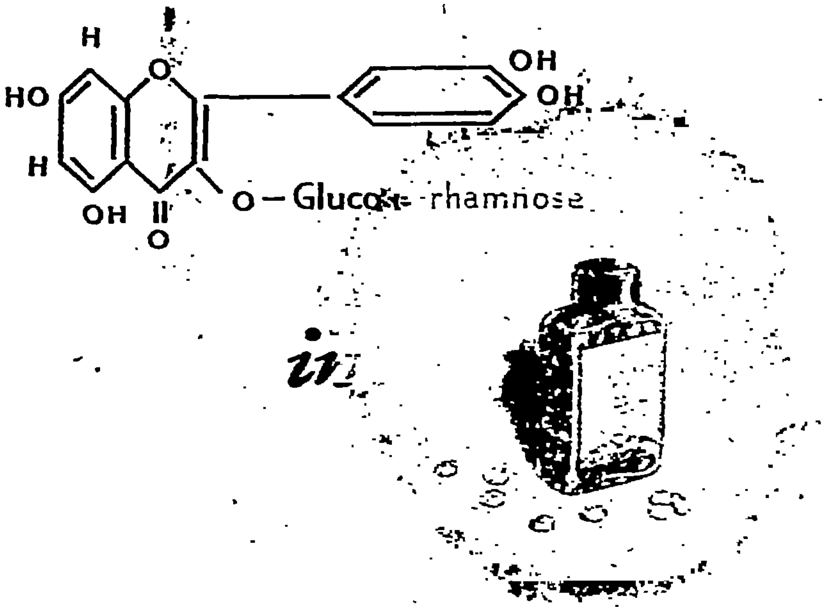
Mr. F. C. DURBIN had followed up 525 cases of *sciatica* and selected 147 cases with neurological signs, treated without operation. Of 123 patients receiving plaster jackets, 79 were relieved or cured.

Mr. G. BLUNDELL JONES had investigated the *penicillin content of the synovial fluid of knees with open war wounds* forty-eight hours after a single instillation of 100,000 units. He found retention, in adequate concentration, provided the effusion was not diminishing. Absorption of fluid led to more rapid disappearance of intra-articular penicillin, but at this stage penicillin was no longer needed in the joint. Penicillin given intramuscularly did not appear in adequate concentration in the synovial fluid of the joint if this was completely immobilised.

Mr. A. L. EYRE-BROOK showed a patient with bilateral cineplastic *forearm stumps* and 2 patients with Krukenberg forearm stumps. The success of the operations (performed by German surgeons) was undoubted, and function appeared particularly good in the Krukenberg stumps because sensation was preserved.

CLINICAL MEETING

Clinical cases were demonstrated at the Princess Elizabeth Orthopædic Hospital by its staff and that of the Mount Gold Orthopædic Hospital, Plymouth. Mr. CAPENER showed cases of lateral rhachotomy for Pott's paraplegia, and his modification of Neufeld nail-plate fixation of pertrochanteric fractures. Mr. G. J. LILLIE showed cases of osteoclastoma and enchondroma treated by radical excision and grafting. Mr. DURBIN presented examples of arthrodesis of the shoulder, showing short tri-fin nail fixation, and of the elbow, showing the value of excision of the radial head. Mr. BLUNDELL



CAPILLARY FRAGILITY

Rutin is a crystalline glycoside obtained from the leaves and flowers of buckwheat. Recent reports attribute to Rutin the property of reducing capillary fragility when this is abnormally raised.

In our research laboratories a limited quantity has been isolated from buckwheat grown in this country and is available in the form of tablets.

Rutin A & H is suggested for administration in hæmorrhagic conditions due to increased capillary fragility or permeability, especially when this condition is associated with hypertension, nutritional deficiency or toxic effects of drugs.

Literature and price on application.

MERSALYL B.D.H.

The Standard Mercurial Diuretic

The use of Mersalyl B.D.H. is indicated for the relief of acute œdematous conditions if it is reasonably certain that there is no severe renal impairment and when the administration of a diuretic over prolonged periods is necessary. When cardiac action is impaired premedication with digitalis may be advisable.

Mersalyl B.D.H. is usually given intravenously, but it may also be given intramuscularly. In less severe cases treatment may consist of one injection in order to induce diuresis which may be prolonged by giving tablets of Mersalyl B.D.H. orally or suppositories of Mersalyl B.D.H. rectally.

Mersalyl B.D.H. conforms with the specification for Mersalyl B.P. and is issued in solution (Injection of Mersalyl B.P.) in ampoules, in tablets (0·08 grm.) for oral administration and in suppositories (0·4 grm.) for rectal use.

Vitamin Therapy—its uses and limitations

SAFER PREGNANCY

Although priority supplies of essential foods are allocated to pregnant women, there still arise cases in which anaemia, fatigue, debility indicate to the physician that all nutritive factors are not, in fact, being assimilated at the level of their physiological requirement. Pregnavite is designed to contain, in a single preparation, those factors most likely to be needed and in doses such as to meet the requirements of most women.

PREGNAVITE

A *single* supplement for safer pregnancy

The recommended daily dose provides:

vitamin A	4,000 i.u.	vitamin B	1 mg	iodine	not less than 10 p.p.m. each.
vitamin D	300 i.u.	nicotinamide	25 mg.	manganese	
vitamin B$_1$	0·6 mg	calcium	160 mg.	copper	
vitamin C	20 mg.	iron	68 mg.

Distribution of Streptomycin

THE frequent appeals by the B.B.C. for streptomycin, sometimes followed next day by notes in the press saying that they produced supplies within an hour or two, have raised doubts whether the drug is being distributed fairly and scientifically or whether ingenuity, luck, a knowledge of the ropes, and even wealth or influence are playing a significant part in the selection of cases. It is unlikely that a single life has been saved in Great Britain by streptomycin obtained from unofficial sources; but it is an unfortunate result of the secrecy imposed on the clinical trials of this drug that no-one can set such doubts at rest. A frank official statement on the supply position, with an explanation of exactly how the cases for treatment are chosen, is needed to clear the air.

Since January, 1944, when SCHATZ, BUGIE, and WAKSMAN[1] first suggested that this antibiotic obtained from *Actinomyces griseus* might be effective against infections which are resistant to penicillin and the sulphonamides, the pharmacology and therapeutics of streptomycin have been studied, mostly but not wholly in the United States, as thoroughly as limited supplies would allow. Its most striking successes have been in *Hæmophilus influenzæ* meningitis; tularæmia; infections of the urinary tract with gram-negative bacilli; and various other gram-negative infections, including meningitis, bacteræmia, and infective endocarditis. There is evidence that it may be effective in plague. But what has raised the greatest hopes, more especially among the public, is its action on the tubercle bacillus. Both in vitro and in animals it was found to be the most powerful drug yet tried, and it was natural that the results of clinical trials received much publicity in the lay press. When it became known that a few cases of tuberculous meningitis were responding to this treatment it was too readily assumed that the long-sought cure for this fatal disease had been found. Since then the parents of every child known or suspected to have tuberculous meningitis have based all their hopes on obtaining streptomycin treatment—and not without reason, since no other remedy holds out any hope at all. On both sides of the Atlantic, therefore, all possible sources of supply have been besieged by the relatives of patients, and their doctors, though there was and is nothing like enough to go round. Unfortunately streptomycin is much more difficult as well as expensive to make than penicillin. In this country three large firms—Boots, Glaxo Laboratories, and the Distillers Co.—have all set up plants for deep culture, but so far the only production estimate published has been one of 250 grammes a month by next June; and the treatment of tuberculous meningitis may require doses of 1–3 g. a day for three to six months; according to HINSHAW et al.[2] the total requirement for a single case may well be 360 g. For the present, therefore, the home product will be useful only for research and the treatment of short illnesses, and we must look to the United States for our main supplies. In America all the streptomycin produced is allocated by a division of the Civilian Production Administration; like other countries, we have been granted a share, but it is unlikely to be enough to treat more than a few hundred cases of tuberculous meningitis, even assuming that most of what we receive is used in that disease. An unknown, but probably much smaller, quantity is imported unofficially, whether in travellers' pockets or through the post; provided the duty is paid there is nothing illegal in this.

The Ministry of Supply has decided that all the streptomycin produced at home or officially imported shall go to the Medical Research Council for distribution, and the council has instituted clinical trials of the drug in six hospitals throughout the country—the Hospital for Sick Children, Great Ormond Street; Hammersmith Hospital; Guy's; the National Hospital for Nervous Diseases, Queen Square; the Alder Hey Hospital, Liverpool; and the Royal Hospital for Sick Children, Glasgow. Other big hospitals have small supplies. The trials, which are apparently confined to children, have now been in progress for several months, and some interim results should soon be forthcoming. Presumably the cases chosen have reached the hospitals concerned through their own outpatient departments or have been sent up in the usual way by outside doctors. The whereabouts of the M.R.C. units have only lately been published, so there are grounds for the suggestion that selection has been largely a matter of luck. Until some way is found to increase supplies only a small proportion of the cases of tuberculous meningitis in the United Kingdom (according to the Registrar-General's returns some 2000 a year) can be treated with streptomycin, but it would do much to satisfy doctors and parents if the claims of each patient could somehow be considered by the research units, so that whether or not a case was chosen for streptomycin treatment would depend solely on its suitability for the trial. The present plan is similar to that adopted by the M.R.C. in its trial of penicillin in infective endocarditis, and there is a close parallel between that disease and tuberculous meningitis in their fatality-rates without specific treatment; but hospitals outside the trial could obtain penicillin for their cases of endocarditis, and sulphonamides also offered some hope of relief. This time the Medical Research Council carries a heavier responsibility, because it has a virtual monopoly of supplies and there is no alternative treatment whatever. As the *Times* of June 6 suggested, it would be a convenience to doctors if there was a central bureau or bureaux to which they could apply when they had a case requiring streptomycin; in London this task could perhaps be undertaken by the Emergency Bed Service of the King's Fund, and outside London by offices connected with the two units at Liverpool and Glasgow. But there is also a need for permanent information bureaux which will know or find out where any scarce drug or piece of apparatus can be found. These would be a useful addition to the National Health Service.

clear relation between predisposition to neurosis nd the stress sustained before breakdown. The nduly high incidence among pilots and air-gunners ould therefore be explained both by the extra esponsibilities they bore, and, particularly in the atter instance, by unsatisfactory initial selection. The latter part of the war saw a renewed interest n selection methods, either by psychological tests or by psychiatric interviews, and the development of objective measures of the effects of operational stress on efficiency and health. The psychiatric interview as a selection procedure was the subject of a large study whose methods and preliminary results are described in detail by SYMONDS and WILLIAMS. Field research in Bomber Command by Squadron-Leader D. D. REID showed the feasibility of using objective criteria—e.g., efficiency in action, incidence of disease, and physical measures such as loss of weight—in assessing the results of exposure to operational strain. Further developments along both these lines were cut short by the end of the war, but enough was learnt for the record to be of interest, not only to the Service doctor but to all concerned with problems of mind and morale.

Responsibility of the Nursing Profession

BY proposing to lengthen the course for State registration from three years to four, and by closing some of the smaller training schools, the General Nursing Council have laid themselves open to much criticism. Their wish to safeguard standards of British nursing is wholly admirable; but the method they have chosen cannot be justified if it entails continued neglect of patients. A leading article in the *Nursing Times* of May 31 says:

> "If the interests of the patients become the sole and even the chief consideration in determining points concerning the training and education of the nurse, the patient's interests will ultimately suffer."

But this argument seems to have been carried too far. The fact that patients are already suffering severely—some, even, to the point of dying, completely untended—is equally cogent.

Admittedly the General Nursing Council are in an awkward position. They have power to dictate a curriculum, but no powers to improve training schools, and no responsibility for the final outcome of their decrees. In face of the present acute shortage of nurses three main courses were open to them: (1) to raise the standard of training in the hope of raising the status of nursing; (2) to lower the standard in the hope of attracting more candidates (a course which no-one would recommend); or (3) to do nothing at all. Of these three alternatives it is not perhaps astonishing that they chose the first. But the pity is that they decided to raise the standard of the theoretical instead of the practical side of the training. Our nursing service, like our Fighting Services, needs a limited number of expert senior officers, and a very large body of capable other ranks, drawn from all parts of the community and properly trained in their craft. The new syllabus would put the State course beyond the scope of the average girl now entering nursing, and since training and staffing are bound up together, the immediate result of the change would be to increase greatly the staffing difficulties of the small hospitals. This seeming disregard of the plight of such hospitals may be due to lack of direct experience of their difficulties among members of the council: of the 25 members 17 are women, and 9 of these are matrons or retired matrons of large training schools, 3 have special interests (mental nursing, the British Red Cross and the Civil Nursing Reserve, the Ministry of Health), 3 are sister tutors, 1 is a health visitor, and 1 is not a nurse. Small hospitals seem to have little voice in the council.

A correspondent in our columns last week made two suggestions which might greatly change the position. With the first of these—that nursing education, like medical education, should have the financial support of the State—few will disagree. If the training school was financed separately from the hospital, and if backward and poorly equipped schools could be helped to improve their level of teaching by well-placed grants, there is little doubt that nursing education would benefit greatly. His second suggestion, however, was more debatable. He holds that the State examination has proved a complete failure, and that the time has come to allow every training school, like every university, to develop its own curriculum and give its own certificate, which should entitle the successful candidate to call herself a State-registered nurse. The chief objection to such a plan is that it might intensify the snob differences which—though the common State examination has done much to dispel them—still linger between different schools. The nurse whose certificate for State registration was granted by St. Pontiff's, the famous London voluntary hospital, would have a much better standing, when it came to applying for a senior post, than the S.R.N. of St. Jude's-the-Obscure in Flintshire. Moreover, nurses' training schools, unlike universities, are exceedingly numerous, and already differ widely—far too widely—in their standards. Any measure that increased that diversity would be unfair to the public, who deserve to know that a S.R.N. has carried out a given set of duties, just as they deserve to know that a doctor has had to cover certain well-recognised ground before he is allowed to register. State registration for nurses has on the whole been a qualified success rather than an unqualified failure. Its weakness has been that it has tried to cater for two types of girl—the one who is fitted to study for a senior post and the one who is not. While there is an excellent case for offering a wide choice of opportunities to girls who take a senior course of study—some, possibly, of university standard—there is equally good reason for making sure that all candidates entering the profession get a thorough and uniform grounding in bedside nursing. It is often asserted that educated and intelligent girls entering nursing would be bored and restless if required to attend such a practical basic course; but a group of senior public-school girls recently questioned took the opposite view: since their school work was almost entirely theoretical, they believed they would find it stimulating, they said, to do something practical for a change. They were also strongly convinced that all who entered must have an equal opportunity of attaining senior posts—in short that all should begin in the ranks and be selected for further training on their merits, as now happens in the Army.

Our correspondent suggested that training schools should receive grants from the State by the same sort of mechanism as universities receive grants from the University Grants Committee. Who then should be responsible for allocating these grants? Given such a duty, the General Nursing Council, from being an academic dictatorship, working in a vacuum, might become truly responsible for nursing education, and able to back their requirements with adequate financial help. If the council carried representatives of all types of hospital they might, indeed, become the body responsible for hospital staffing throughout the country. Power is said to corrupt, but coupled with responsibility it often sobers and strengthens. In any event the task of regenerating nursing must be left largely in the hands of the nursing profession itself.

Sterilisation of Instruments

In our leading article of May 17 we argued that autoclaving and dry heat are not always applicable to glass-metal syringes, and that boiling is perfectly satisfactory if certain precautions are taken. Correspondents have pointed out that some spore-bearing organisms are not killed by boiling, and many doctors are evidently worried on this score. In fact, infection of the meninges by spore-bearing organisms, other than *Bacillus subtilis*, have not, so far as we know, been recorded, and the vast majority of these infections have occurred where the most elementary lapses of aseptic technique have crept in. It is probably true to say that, except in serious emergency, spinal anæsthesia should not be attempted unless the operator has access to a syringe which has either been autoclaved or sterilised by dry heat, so that he can be certain that no viable organisms or spores are present. Yet it is clear that for all other forms of injection the risk from spore-bearing organisms is exceedingly small. Boiling for 10 minutes, especially if sodium bicarbonate is added, does in fact kill the vast majority of spores; and boiling is the only method within the scope of the general practitioner. The sodium bicarbonate, however, must be removed before the syringe is used, since it reacts with many solutions.

A correspondent this week suggests that solutions other than water may be used. Sucking up hot oil is widely employed for this purpose, but it has been criticised on the ground that the oil does not penetrate between the barrel and the cylinder, and that tests have shown this method to be unsafe. Boiling methylated spirit has also been suggested, but with this method there is obvious danger of fire. Hypertonic solutions with a boiling-point above 100°C have also been used, but with these it is necessary to remove all vestige of the solution from the syringe, and autoclaved water would probably not be available.

However, the most important point is that the vast majority of infections following injections are due, as we have said, to organisms which can readily be killed by boiling. If doctors in general would finally discard antiseptic solutions of any kind and rely on boiling for all injections, other than those into the theca, very little would be heard of syringe or needle infection.

Annotations

CONSCRIPTION AND VENEREAL DISEASE

In the House of Lords on June 3 Lord Moran gave a disquieting account of the prevalence of venereal disease among our soldiers abroad. As will be seen from the report on another page, he quoted annual new-infection rates of 228 per 1000 for Japan, 185 for Germany, 168 for Austria and Italy, and 141 for Burma and Malaya. These figures contrast very unfavourably with the rate for the Army at home, which is itself none too low at 33. They recall the high incidence of venereal disease in our Army of the Rhine in 1919.

Lord Moran was speaking on the National Service Bill, and he suggested that, since conscription as now contemplated will apparently do little or nothing to give this country security in time of war, it is really being proposed as a means of providing armies of occupation. Yet the use of conscripts overseas was, he said, a policy which no democratic European government had ever countenanced; and he was profoundly concerned at its effect on health and morale. Absence from home was the vital factor in the high incidence of venereal disease now reported: too often, moreover, "the men have no healthy means of distraction. They lead a mechanical life, they have not enough to do, and they are just waiting for the time to get out." The figures lent no support to the idea of the Army as a people's university, teaching men citizenship:

> "The most friendly critic of the Army must feel that these figures mean that during the conscript's time abroad his experience in the Army is a demoralising experience. To segregate young men at the beginning of their life, under these conditions, is a very poor preparation for the more serious view of life which is so sadly needed at the present time."

The alternative which Lord Moran preferred to conscription was voluntary recruitment for the Army—which in his opinion has not yet really been tried. Hitherto the soldier leaving the Army has had no guarantee of getting regular work, though Lord Moran was glad to learn that provision was in future to be made for fitting such men into civil life.

On the immediate problem of the young soldier serving abroad, Lord Nathan, replying for the Government, agreed that the incidence of venereal disease is serious and demands proper and prompt action. Intense thought was being given to it by the military authorities, and admirable work had been done by the chaplains, by the educational and welfare services, and by commanding and regimental officers. "But on the whole," added Lord Nathan, "we must rely upon the reflection in conduct abroad of what these young men learn at home"; and he put his faith, in the final instance, in a "correct upbringing." To this it may be answered that no Service which in time of peace compulsorily removes boys of 18 to an unfavourable environment can divest itself of a grave responsibility.

TUBERCULOSIS CONTROL IN MINNEAPOLIS

A sanatorium of 750 beds has today 150–200 of them vacant. Such a statement makes us automatically despair of the ever-present shortage of staff; but, when we read further that these 150 beds, fully occupied twelve years ago, are empty for lack of anyone to put in them, despair gives way to astonishment. Such a state of affairs has arisen in Minneapolis, and is attributed to a tuberculosis control programme started there in 1920.

According to Myers[1] a mortality of 120 per 100,000 in 1920 fell to 27·1 by 1945. The decrease in the incidence of infection is reflected by extensive tuberculin-testing, on which the control scheme is mainly based. For ample, in 1926 a representative group of children oduced 47·3% positive reactors; in 1936 a similar oup showed 18·9% positive; and by 1944 a further oup had only 7·7% of reactors. Undoubtedly several ctors are responsible for such reduction in infection. yers believes the most important to be (1) prevention cases of the reinfection type of disease from becoming fectious, by early treatment; (2) isolation of the fectious in institutions or at home; and (3) eradication tuberculosis in cattle.

---

[1] Myers, J. A. *Publ. Hlth Rep., Wash.* 1946, 61, 1563.

After extensive tuberculin-testing, all positive reactors er the age of 12–14 years are radiographed yearly. his is feasible because of the comparatively small oportion of positive tests. In adults radiography ery six months is recommended. Radiography of ildren under 12–14 years so rarely revealed serious sease that its routine use has been discontinued.

In dealing with primary infections all forms of therapy ve been abandoned, and the funds thereby saved are plied to more extensive tuberculin surveys, search for urces of infection, and radiography of adult reactors tuberculin. Very different is the attitude to the infection type of disease. Minimal lesions, apparently nsidered non-infective, are treated by ambulatory eumothorax. In this way it is hoped to prevent ore serious disease and its associated infectivity. hould such therapy for any reason be contra-indicated, ese cases are treated in common with the frankly open" cases in hospital. Though primary tubercusis has been seen to develop in over 1000 adults, such te first infections are believed to be no more hazardous han those occurring in childhood. Further, such dults do not develop the reinfection type of disease more han do others of the same age.

It is an interesting and successful demonstration of uberculosis control by lowering the incidence of infection, s distinct from raising the resistance by vaccination. yers holds that such a low incidence is safe and esirable. This control programme is not as a whole pplicable to centres in this country, but there are essons to be learnt, and it remains a fact that in inneapolis there are 150 beds begging for patients.

THE SOUTH AFRICAN FOSSIL "APE-MEN"

OVER twenty years ago Prof. Raymond Dart, of the Witwatersrand University, described the fossil skull of an extinct ape-like creature discovered in limestone deposits at Taungs in Bechuanaland. Pointing to certain strikingly human characters of the skull and dentition, he gave the name Australopithecus to the fossil. Later, more remains of the same type of creature were discovered by Dr. R. Broom, F.R.S., in limestone deposits not far from Johannesburg, and these are now all regarded as representatives of a common subfamily, the Australopithecinæ. Quite recently these fossils have once more come prominently into the news. There are three reasons for this: (1) the publication at the end of last year of a comprehensive monograph by Broom and Schepers[1] on all the remains discovered up to that time; (2) the discussion on their significance at the Pan-African Congress on Prehistory held at Nairobi last January; and (3) the discovery by Dr. Broom within the last few weeks of a new skull (almost complete except for the mandible) as well as portions of jaws showing more details of the permanent and milk dentitions.

At a meeting of the Zoological Society in London on May 13 a detailed account of the australopithecine material discovered up to the end of last year was given by Prof. W. E. Le Gros Clark, F.R.S., who has lately made a personal study of the original fossils in South Africa. Their main anatomical features can be summed up briefly. The general proportions of the skull are simian, with a relatively small brain-case and massive jaws. The intracranial capacity in the adult must have reached about 600 c.cm. and thus falls within the simian range; however, it is probable that the brain-weight/body-weight ratio was rather higher than in the modern large anthropoid apes, for the fragments of limb bones so far discovered indicate that the Australopithecinæ were relatively lightly built creatures. In the details of the skull and dentition there are several characters which differ significantly from those of the modern apes and make a remarkable approach to the Hominidæ. These include the contour of the supraorbital region, the relation of the frontal pole of the brain to nasion and glabella, the relatively weak development of the temporal ridges and the nuchal crest, the conformation of the glenoid cavity, the contour of the zygomatic bone and the "set" of the zygomatic arch, the relatively forward position of the foramen magnum, the persistence of the sutures on the roof of the skull after the eruption of the third molar, the shape of the palate and dental arcade, the relatively small size of the permanent incisors and canines, the nature of the wear of the permanent molar teeth, the cusp pattern of the first lower milk molars, and the diminutive size of the milk canines.

The new skull discovered by Dr. Broom on April 18 of this year confirms many of the inferences already drawn from less complete material. Those who are acquainted with the comparative anatomy of human and simian skulls will recognise from Dr. Broom's drawings and photographs in *Nature*[2] and the *Illustrated London News*[3] that this new australopithecine skull (which belonged to an old individual) shows human characteristics not to be found in fully mature ape skulls—particularly in the contours of the frontal and occipital regions and in the inclination and set of the orbits. There is also some reason to suppose, from these illustrations, that the flexion of the basicranial axis approached to some degree that characteristic of the human skull. The hominid characters of the skull and dentition of the Australopithecinæ are paralleled in a remarkable way by the limb bones, of which several fragments have so far been discovered (the lower end of a humerus, the upper end of an ulna, a talus, the lower end of a femur, and a capitate bone). The talus and the capitate bone show a curious mixture of simian and human features, but the other limb-bone fragments would probably have been assigned to Homo if they had been found unassociated with other parts of the skeleton. They certainly indicate that the australopithecine apes were capable of standing and walking with an erect posture closely approximating to that of man. This inference is supported by indirect climatological evidence that the country in which they lived was probably rather arid, and certainly not forested like the habitat of the modern anthropoid apes. Presumably, therefore, they must have been adapted for a terrestrial rather than an arboreal mode of life.

The significance of these remarkable South African fossils in the study of human evolution is likely to provoke discussion. Certain facts, however, seem well assured. They are clearly representatives of the Hominoidæ—the name given by Simpson[4] to the superfamily which includes in a common zoological group man and the anthropoid apes. They differ in many important respects from all the modern large anthropoid apes (and from all the extinct large anthropoid apes yet known) and in almost all these respects show closer resemblances to the Hominidæ. This is no longer a matter of dispute among those anatomists who have made a careful systematic study of the remains. The problem now resolves itself into the question of what these resemblances signify. If the usual morphological criteria for assessing zoological relationships are accepted, it must obviously be concluded that the Australopithecinæ are much more closely related to man than are the modern anthropoid apes. The possibility must no doubt be considered that their hominid characters are, so to speak, fortuitous, in the sense that they might be the expression of a parallel or convergent evolutionary process. But the resemblances are so numerous, detailed, and intimate, that this interpretation seems far-fetched. Whether the fossils have an ancestral relationship, direct or indirect, to *Homo sapiens* can only be finally determined when their geological age is accurately known. The type of the associated fauna has led local prehistorians in South Africa to the general conclusion that they are probably of Pliocene age; and, if this proves to be so, the fossils may well have been representatives of the ancestral stock which gave rise to the Hominidæ. If it were shown by further geological studies that they are of more recent date, they could at most be regarded as late (and apparently little modified) survivors of such an ancestral stock. These seem reasonable inferences from the data so far available, and from the strictly anatomical point of view there appears to be nothing to preclude an ancestral relationship.

---

[3] *Illustrated London News*, May 17, 1947, p. 508.

[4] Simpson, G. G. *Bull. Amer. Mus. Nat. Hist.* 1945, 85, 1.

Some of those who have studied the australopithecine fossils have expressed doubt whether they should be regarded as a very progressive type of ape or an exceedingly primitive type of man. This doubt is readily understood when the anatomical details of the skull, dentition, and limb-bones are considered in detail one by one. Dr. Broom refers to these creatures as "ape-men," and this general and non-committal term has much in its favour. In his discourse at the Zoological Society, Professor Le Gros Clark suggested that, in view of the relative size and proportions of the brain, it might be desirable (pending the further evidence which is now accumulating) to adopt a conservative attitude by calling them apes rather than ape-men. He also urged that final and emphatic statements about their relation to the origin of man should be avoided for the present, since the discoveries during the last few weeks, and those likely to be made in the near future, will certainly yield much more information.

EDINBURGH AS POSTGRADUATE CENTRE

As might be expected from its ancient teaching tradition, Edinburgh is not lagging in its organisation of postgraduate education. In the last few years great difficulties have been surmounted; and the recent appointment of Major-General Sir Alexander Biggam, late consulting physician to the Army, as director of postgraduate studies, reflects the importance attached to further development in this sphere. The criticism that the Royal Infirmary contains too few patients for the proper training of postgraduates, in addition to large undergraduate needs, is more than ever valid in the present post-war rush. The Edinburgh Post-Graduate Board for Medicine has therefore looked elsewhere for its clinical material; and students are conveyed to the three large municipal hospitals, to special hospitals, and to the Royal Infirmary's rehabilitation centre. These are situated within easy reach, so little time is spent on the journeys. With sections of classes visiting these centres in rotation, the experience is wider than would be obtained by continuous instruction in the same general hospital; and the presence of postgraduate students in the various hospitals provides an additional stimulus to the staffs. The eventual aim is to establish a separate school for postgraduates, physically near to, but administratively independent of, the Royal Infirmary. There is little hope of new building within the next decade, but as an expedient the use of one of the smaller existing hospitals in the city would temporarily meet this need. At present the board is conducting short refresher courses and four long courses per year—two in internal medicine and two in general surgery. Applications for enrolment far exceed vacancies, and selection candidates according to qualifications and experience is made.

Edinburgh was always known as a gathering-point for overseas students, and the present postgraduate classes contain an ever-increasing number of graduates from South Africa, Canada, India, and other parts of the world. Undoubtedly some Dominion visitors, particularly those from Australia and New Zealand, who formerly came in large numbers, are deterred by the fear that they may not find accommodation. The board helps, where it can, by passing on the addresses of recommended lodgings and private hotels; but their number is often insufficient, and the authorities are seeking to buy a building capable of housing 80–100 students. The university must now be regretting that it did not take, or was not offered, the chance of purchasing the houses of University Hall—formerly run, principally for undergraduates, by the Town and Gown Association—which were sold at the end of the war.

Most other medical schools will acknowledge their debt to Edinburgh's example in the arrangement of systematic teaching, and they will still find novelties. For example postgraduate students are asked, at the end of each course, for their frank criticism of the arrangements for their instruction, and many of their proposals have been incorporated in the programmes of the classes.

RADIUM TODAY

THE Cancer Act of 1939 is now superseded by the National Health Service Act of 1946, and most of its provisions will be carried out by the new regional boards. The Radium Commission [1] strongly urge that every region should have a cancer organisation, under the wing of the regional board, to help in planning cancer treatment. From their long experience they suggest that this organisation should see that there are facilities for early diagnosis, treatment by trained specialists, follow-up, records, and research, and should make sure that these facilities are fully used by all concerned. The many difficulties to be overcome include lack of specialists (both surgeons and radiotherapists), and inadequacy of buildings and equipment, while further research will be needed to exploit recent discoveries in nuclear physics. The reports from the various centres indicate how some of these difficulties may be overcome, but through every report runs the same story—new building is essential. Birmingham has produced a cancer scheme for the West Midlands, but this depends on the opening of a new block at the Queen Elizabeth Hospital, for which an "A" licence has not been obtained. Leeds is seeking authority to add a new block to the present X-ray department. Liverpool must erect temporary accommodation. Newcastle has to treat patients in three hospitals, one at a considerable distance, which is extravagant both in the time of the specialist staff and in the use of specialist equipment. Manchester is fortunate in having obtained a licence to add an additional story to a ward block, but this must be followed by further building to make room for necessary equipment and services. It is easy to see how centres faced with so many obstacles can be helped by an advisory body, such as the Radium Commission. The evolution of specialist services for cancer can be properly controlled only if expert opinion is to be had when difficult decisions must be made.

The work done by the technical committee is also important. Large quantities of radium have been turned over by the Radium Trust for the increasing work of the commission's centres, and though there is still a bottleneck in the making and filling of containers, radium is gradually reaching the centres and enabling clinicians to try new methods of treatment. Particulars of the new types of container which have been measured and accepted during the year 1945–46 are given in an appendix to the commission's report—a valuable list of the approved types which will be helpful to hospitals when ordering new radium. The use of radon is also being brought under control. Under an arrangement with the Medical Research Council the radon centre at Barton issues radon only to hospitals which have been approved by the commission, and such approval is given only to those hospitals which have a radiotherapeutic department properly organised and equipped, and where the use of radon is suitably supervised.

PLANS OF THE R.M.B.F.

Westmoreland Lodge, the home for old people sponsored by the Royal Medical Benevolent Fund, is nearing its date of opening. In his report on the R.M.B.F.'s work presented to the annual general meeting on June 5, Mr. R. Handfield-Jones, F.R.C.S., spoke of this project as particularly dear to Sir Arnold Lawson, the late president, who before he died was able to ensure that a suitable house had been bought. This stands in its own grounds near Wimbledon Common, conveniently placed for bus routes to Wimbledon and Putney. It will contain enough single-room flats to receive twelve elderly ladies capable of looking after themselves, doing their own shopping, and cooking their own breakfast, tea, and supper. Midday dinner will be provided at a very low cost and served in the common dining-room and lounge. Residents will be independent, living with their own furniture round them, but the fund will supply central heating, hot and cold water, a gas or electric fire, and a gas-ring in each bed-sitting-room. The house has cost £7000, and repairs and alterations are estimated at a further £5000. Annual expenses will include rates, wages, garden, insurance, light, and heat. If Westmoreland Lodge proves a success the managers of the fund hope to open another home, possibly for elderly men, or possibly for the sick who need nursing. Meanwhile the undertaking has called for courage, and Mr. Handfield-Jones trusts that it will be cordially supported. The council of the British Medical Association have allocated £200 to it, and Mr. Handfield-Jones asks all the fund's subscribers, when sending their annual subscriptions, to add a special additional cheque or banker's order marked "Westmoreland Lodge." The profession should look after its own, when they fall on evil times, and he is confident they would resent outside assistance, in spite of the many opportunities of appealing to the general public which offer from time to time. He asks that, besides giving himself, every subscriber should enlist another during the year.

At the annual meeting Sir Alfred Webb-Johnson, P.R.C.S., was elected to succeed Sir Arnold Lawson as president. Dr. C. L. Batteson will remain treasurer, and Mr. V. H. Riddell, F.R.C.S., succeeds Mr. Handfield-Jones as hon. secretary.

PRESIDENT TRUMAN AND NATIONAL INSURANCE

On May 19 President Truman in a special message asked the United States Congress to give "immediate attention" to the question of enacting a national health programme to assure that "the opportunity for good health be made available to all, regardless of residence, race, or economic status." He stated that in November, 1945, he had in a message to the last Congress outlined a long-range health services plan, and that certain advances in the directions he then indicated had been made; but he urged the need for further effort to provide: (1) adequate public health services; (2) additional facilities for medical research and medical education; (3) more hospitals, and more doctors, dentists, and nurses; (4) insurance against costs of medical care; and (5) protection against loss of earnings during sickness. He laid special stress on the need for further research in the prevention and cure of disease, and for expanded educational facilities to meet the shortage of medical personnel, which is now severely felt, particularly in the rural areas, and would, he said, "continue to plague the nation until means are found to finance modern medical care for all of our people." The main conclusion to which Mr. Truman's review of the situation leads him is that "national health insurance is the most effective single way to meet the nation's health needs. Hitherto the American advocates of national health insurance have encountered formidable opposition from influential quarters—notably from the American Medical Association—and they appear to have achieved but little success in their efforts to secure legislation to carry their prospects into effect. But during Mr. Roosevelt's long period of office compulsory insurance against unemployment and old age was introduced and met with general acceptance, and it seems possible that familiarity with the practical working of these forms of social security may have removed much of the hostility to the form of social security that provides medical care through national insurance. In his latest message Mr. Truman states that he regards health insurance as "a logical extension of the present social security system which is so firmly entrenched in our American democracy"; and he concludes:

> "The total health programme which I have proposed is crucial to our national welfare. The heart of that programme is national health insurance. Until it is a part of our national fabric, we shall be wasting our most precious national resource and shall be perpetuating unnecessary misery and human suffering."

REMUNERATION OF SPECIALISTS

Some time ago the Minister of Health and the Secretary of State for Scotland appointed a committee to recommend "what ought to be the range of total professional remuneration of registered medical practitioners engaged in the different branches of consultant or specialist practice in any publicly organised hospital and specialist service." The membership of the committee has now been announced as follows:

Sir Will Spens (chairman), Mr. C. R. Dale, Sir Thomas Gardiner, Mr. T. Lister, Miss Elizabeth Looker, Prof. D. Murray Lyon, F.R.C.P.E., Lord Moran, P.R.C.P., Mr. Leslie E. Peppiatt, Prof. Harry Platt, F.R.C.S., Dr. S. Cochrane Shanks, F.F.R., Mr. J. R. H. Turton, F.R.C.S., with Mr. T. B. Williamson (Ministry of Health) and Dr. D. P. Stevenson (assistant secretary, British Medical Association) as joint secretaries.

THREE MONTHS' POSTPONEMENT

The day appointed for starting the National Health Service and the related schemes of social insurance has been changed from April 1 to July 5, 1948. In his statement last Monday the Prime Minister pointed out that "the various schemes are closely linked up with each other and with proposals for completing the break-up of the poor-law, and providing a comprehensive scheme of national assistance, standing behind the insurance provisions." A Bill to end the poor-law will be introduced next session, so that all the schemes can be brought into operation on the same day.

We regret to announce the death of Mr. John Crowlesmith who retired last year from the board of directors of Messrs. Hazell, Watson & Viney, printers of The Lancet. Eighty-six years of age, he joined the firm in 1882, and for the last 25 of his 64 years' service he was our valued associate in the production of this journal. He held office as president both of the London Master Printers' Association and of the British Federation of Master Printers, and he leaves happy recollections with all who worked with him.

eir treatment in the ward while at the same time her rderlies are re-educating the up-patients in walking. n the physiotherapy department patients with chronic ronchitis and emphysema are given group exercises to ncrease diaphragmatic movement, while those who need use the spirometer. Patients with lesions in the osterior columns of the spinal cord are given Frenkel's xercises to re-educate their kinæsthetic and proprioceptive sense, watching and checking their own movements in mirrors.

Control of intention tremor in disseminated sclerosis.

It seems useful to mention here the practice at another hospital—St. Helier, Carshalton. There, too, the nursing situation is acute, and has compelled this large general hospital to restrict its geriatric unit to two wards of thirty beds each. But St. Helier has the advantage of new buildings and lavishly equipped physiotherapy and occupational therapy departments, and has made use of these to develop outpatient treatment on an unusually wide scale. Many old people who cannot be found beds in the wards are collected daily in a Ford shooting-van, to attend exercise classes, receive physical treatment, and spend some hours in the occupational therapy department. The van runs a shuttle service, delivering three groups of patients daily, and taking them home again; and the members of each group naturally soon form a friendly and emulous club. Exercises are given early to hemiplegics, to strengthen backs, arms, and legs, and prevent contractures; and many of the patients have rheumatic and arthritic troubles which respond to treatment. A large ward has been equipped as a gymnasium, and contains, besides, six cubicles with couches, where radiant heat and other forms of physical treatment can be given. The occupational section contains benches for carpentry, and large looms, as well as rug-weaving looms which demand much use of the fingers, and small box looms which can be used in the wards.

THE USE OF SPRINGS

At Orsett, bed-patients are helped to exercise their muscles by some ingenious devices. The paretic and rheumatic limb have this in common with a prosthesis: the patient is aware of their weight. If some of the weight is lifted, movement can be much more easily effected and controlled; that is why exercises in the warm pool are so successful with young patients. Old people, however, can hardly be subjected to such measures, and Dr. Cosin therefore uses helical springs of varying tensions to help movement of the limb by reducing its effective weight. Springs of appropriate tension are attached to a balkan beam above the bed; linen slings, fastened to the free ends of the springs, carry the weight of the patient's arms or legs. If the patient needs to make an upward movement he has some slight support which encourages him to attempt it; if he needs to bring a hand or foot down to the bed he must overcome the slight resistance of the spring, which exercises the muscles used. Since gravity acts in the opposite direction to the spring this slight resistance is never too much to be overcome. This constant gentle exercise is applied to rheumatic arms and legs, to limbs recovering from paralysis due to a stroke, to limbs crippled by rheumatoid arthritis, to legs recovering after fracture of the femur, and to the incoördinate arms and legs of patients with disseminated sclerosis. Backs which need support are exercised on the same principle: a loosely padded linen back-sling, with a groove down the middle to allow room for the spinous processes of the vertebræ, is attached to two springs fastened to the foot of the bed. The sitting patient receives, from this sling, constant gentle lumbar support which reinforces his efforts if he wants to lean forward, and must be overcome if he wants to lean back on his pillows. The lumbar muscles are thus constantly mildly exercised, and respond by gaining strength.

Cases of hemiplegia, if straightforward and mild, are provided with springs and slings within a few days of the stroke. Light plaster splints may also be used to prevent contractures of the paretic limbs—for example, to maintain dorsiflexion at the wrist. Contracture of the pectoralis major can be prevented by an appropriately designed spring apparatus. Exercises are given, and in uncomplicated cases the patient is approaching reablement in six weeks. Incidentally, exercises can improve many other conditions. The intention tremor which gives so much trouble to the disseminated sclerosis patient can be largely overcome by the use of appropriate exercises; and even in such a hopeless and progressive condition as Friedreich's ataxia, severe disability can be long postponed. These conditions are not found in old people, of course, but patients afflicted with them are likely to be found in hospitals for the chronically ailing and the old.

THE FRACTURED FEMUR

The common accident to the elderly, fracture of the neck of the femur, is actively treated. His aim being to get early active movement without weight-bearing, Dr. Cosin prefers to pin intracapsular fractures of the femur rather than to treat them by extension. The shock of moving a patient in an extension apparatus on and off the bed-pan several times a day is greater than that of operation with a skilfully administered anæsthetic; and the care of the back is made much simpler if the patient is able to move about in bed. The Roger-Anderson apparatus, which applies well-leg traction, has proved suitable though not ideal in the treatment of the pertrochanteric fracture, because though the patient's legs are immobilised he can exercise his back muscles freely. In this method of treatment the weight of the plaster is partly carried by a spring and sling. Skeletal or skin traction is not often used because, by tending

Pertrochanteric fracture of femur treated by well-leg traction and springs.

to immobilise the patient on his back, it not only encourages pneumonia but adds greatly to nursing difficulties. At 70 or 80 a perfect anatomical result is less important to the patient than an early escape from bed, with bony union even if there is some shortening.

At Orsett the scarcity of good trained staff has made it difficult to foster the same enthusiasm for this kind of work which has grown up at the West Middlesex; and this is reflected in a slightly different spirit among the patients. Certainly the women are on the whole brisk and interested, but the senile old men are torpid and sluggish with little taste for any sort of activity. Whether a good part-time nursing scheme, in the Gloucestershire tradition, might alter this is something which the Essex County Council is taking steps to find out. Where such good work is already being done it seems a pity not to ensure that it is done under the best possible conditions.

Gloucestershire Hospitals

In Gloucestershire a soundly planned part-time nursing scheme[1] has benefited the old people in hospital. These nurses—who are not mere supernumeraries but form the actual staff of the hospitals—are drawn from every quarter of the county, and are picked up every day at approved collecting centres and carried to and from work, at the authority's expense, by taxi. Some are State-registered nurses, some assistant nurses; some when engaged have had a little previous nursing experience, some have had none. All are accepted, given responsibility appropriate to their standing, and trained to take more. They are asked to give just what time they can afford from other duties; and in practice the four-hour unit of service has proved acceptable, many nurses working this span on six days a week, others on two or three days. Their uniform is provided and laundered, and they are given a meal on duty.

One result of this modern scheme has been that the old people in infirmaries are now well cared for in fully staffed wards. A second, even more important, result is that the programme of medical and surgical treatment can now be greatly expanded. In the days of the shortage, treatment had to be reduced to its simplest terms because the nurses were too hard-pressed to attend to detail. No physiotherapist was attached to the hospitals at the time, which meant that the measures used successfully at Orsett could not be developed; but the county is now advertising for two physiotherapists and an occupational therapist. Already much is being done. Old people who had been kept unnecessarily in bed, simply because there were not enough nurses to get them up and dress them, are now getting about; and others will be able to join them when they have been given a few simple exercises and possibly some massage. Dr. T. B. H. Haslett, the consulting physician, would like to see a comfortable old people's home associated with the hospitals, to which those who have no homes of their own could be sent when they are fit. Gloucestershire had a good home of the kind, but has been obliged, owing to shortage of beds, to use it as a maternity hospital for the past five years; which means that many reabled old people have had to remain in the infirmaries.

SOME PROSPECTS

Those capable of such recovery include hemiplegics who have never been allowed to grow contracted and bedridden; patients with heart-failure who have profited by small doses of digitalis, mercury diuretics, and breathing exercises; patients with chronic bronchitis, who also benefit from breathing exercises, coupled in their case with small doses of ephedrine and perhaps inhalation of penicillin spray; and diabetics whose disease has been stabilised. With the help of a physiotherapist it will be possible to get many old people crippled with arthritis on to their feet. Attention to salt and water metabolism, blood-transfusion, and penicillin have all helped to make surgery safer for old people. Active treatment of all kinds in the infirmaries will in time encourage doctors to send in their old patients early instead of as a last resort; and the rise in standards of nursing is already changing the attitude of prospective patients: they no longer dread admission to hospital. Even old and forbidding buildings have changed their character with the help of light paint and the birth of an eager spirit in the staff.

Orsett and Gloucestershire, both doing good work for the old, present an interesting contrast in methods: one being founded on advanced physiotherapy with a minimum of ordinary nursing, the other on an able and numerically adequate nursing staff. While it is probable that a combination of both these services will give even better results, it is also clear that good schemes can be developed even in the presence of great handicaps.

Special Articles

GENERAL MEDICAL COUNCIL

AT the 171st session of the council, after the President's address, reported last week, 28 penal cases were considered.

Penal Cases

The name of *Herbert Stanley Arnell* was restored to the Dentists Register after penal erasure.

ALLEGED NEGLIGENCE AND COVERING

Chandra Shekhar Jagannath Dan De Kar, registered as of 24, Marden Road South, Whitley Bay, Northumberland, L.M.S.S.A. (1935), appeared in answer to five sets of charges:

(1) A conviction before magistrates in December, 1946, of failing to register dangerous drugs on 5 occasions and irregularly procuring them on 2 occasions; (2) in October, 1944, operating on a patient for scrotal hernia in his surgery without another registered medical practitioner being present; negligence in allowing the patient's face to be burnt and one of his arms to become paralysed, in sending him home in a few hours, in not visiting him that day, and in failing afterwards to treat or advise him properly for his injuries; negligence in operating on the hernia, so that a further operation was necessary; (3) in December, 1944, performing subtotal hysterectomy in his surgery without another registered medical practitioner being present; sending the patient in an ambulance after $3^1/_2$ hours, unaccompanied by a registered medical practitioner or a State-registered nurse, to her home, where she died two days later; negligence in and after the operation; (4) in April, 1945, removing tonsils and adenoids from a boy of 16 at his surgery, immediately after his first examination, without another registered medical practitioner being present; the respondent (the charge alleged) gave the anæsthetic, an unregistered person continued it, and the patient died without regaining consciousness; the performance of the operation was in all the circumstances an act of negligence; (5) signing blank prescription forms to be filled up by his nurse, thereby knowingly enabling her to treat insured persons and engage in professional practice as if she were qualified and registered.

Dr. Dan De Kar was accompanied by Mr. C. Paley Scott, K.C., and Mr. Norman Black, counsel, instructed by Messrs. Bentleys, Stokes, and Lowles. Mr. Gerald Howard, counsel, instructed by Messrs. Waterhouse, presenting the case for the G.M.C., said that the respondent had prescribed morphine sulphate for two of his insured patients who did not need it, and had received the drug himself. The doctor, after operating on the patient for scrotal hernia, had sent him home in an ambulance while still unconscious, and in spite of repeated telephone calls had not visited him till the next evening, and had not prescribed either for the burn or for the paralysis. He had charged a fee of 12 guineas. The operation for subtotal hysterectomy had been performed on a married woman of 31. The post-mortem examination, performed by the police surgeon, had not stated the exact cause of eath, nor confirmed the doctor's diagnosis of cancer. he youth upon whom the doctor had operated for nsillectomy had died on the operating-table. The only ersons present at these operations beside the doctor had een: a State-registered nurse, Miss Evelyn Adamson, nd an unregistered woman assistant.

The signing by the doctor of blank prescription forms ad been disclosed in the evidence of the doctor and iss Adamson in proceedings taken against them at ewcastle assizes for conspiring to obtain payment from he local authority by false pretences, of which charges hey had been acquitted. Dr. Dan De Kar had there dmitted, and Miss Adamson had confirmed, that he abitually left half a dozen signed forms with her when e went on his rounds. Forms had been produced bearing is signature and made out in Miss Adamson's handriting for iodoform gauze, white wool, aspirin, and over's powder. Mr. Howard called evidence in support f the charges.

The patient with scrotal hernia said in evidence that he ad been unable to have the operation performed in hospital ithout a long delay. On entering the operating-room he had een only the doctor, Miss Adamson, and a girl smoking a igarette and arranging instruments. He had been given a eneral anæsthetic, he did not know by whom. The doctor as in his shirt-sleeves and a rubber apron; the women ere not wearing gowns. His arm had remained paralysed or about 8 months. The doctor had visited him to take out titches, and had made him a belt, which he had not worn, but had not treated or prescribed for his face or arm injuries. The husband of the deceased woman patient said in evidence that he had been serving overseas at the time of the operation and had authorised it in writing. He had complete confidence in the doctor, who still attended him and his children. The father of the deceased boy said that the boy had suffered from infected tonsils and adenoids all his life. He had had an anæsthetic before. The father had complete confidence in the doctor and had signed a letter sent to the council by the branch committee of his trade-union asking that the doctor's name might be kept on the register.

Dr. Dan De Kar, giving evidence on his own behalf, said he had obtained the licence of the Bombay College of Physicians and Surgeons at the age of 20, and had qualified in England in 1935. He had studied for some time under Prof. G. Grey Turner. He had devoted himself exclusively to hard work, playing no games and taking no holidays. He had always been keen on surgery and had assisted Professor Turner and other eminent surgeons. He had equipped his own theatre when building the house in 1938. He had a waiting-room, a consulting-room with three cubicles, an ante-room, and the theatre. He had performed nearly 2200 operations there, mostly for the removal of tonsils, and apart from the two deaths mentioned in the charge had had only one other fatality. No medical help had been available in war-time, but Miss Adamson was highly qualified and competent. He had himself given the anæsthetics —A.C.E. mixture—and both he and his assistants had worn proper clothing. The deceased woman patient's uterus had been septic and invaded by a large malignant growth; her general condition had been poor. He had himself accompanied her home in the ambulance and had seen to her disposal in bed, and he had sent home for sheets of his own to put on the bed. He had visited her at frequent intervals until her death. Dr. Dan De Kar had no idea of the cause of the paralysis of the arm of the patient with scrotal hernia; at operation the arms had certainly not been overhanging the table. The burn was probably due to chloroform. No complaint had been made to him at the time. He admitted signing blank prescription forms to enable Miss Adamson to fill in details of routine medicines and appliances. She had never prescribed a dangerous drug nor any medicine that had not already been ordered by the doctor. This practice had been necessary to enable the great volume of work to be handled, but he had discontinued it. He undertook to perform no more operations at his own premises.

The council found the convictions for offences against the Dangerous Drugs Acts proved, and on this charge suspended judgment for two years, subject to the doctor's good conduct in the interval and his production of testimonials at the adjourned hearing. They found the charge respecting the operation for scrotal hernia not proved to their satisfaction. They found that the doctor had performed the operation for subtotal hysterectomy without another qualified or registered person being present, and had caused the patient to be taken home in an ambulance about $3^{1}/_{2}$ hours afterwards, but not that she had been unaccompanied by a doctor or nurse, nor that he had been guilty of negligence in this case, nor that the facts disclosed infamous conduct in a professional respect. They found that the performance of the tonsillectomy operation was an act of negligence not amounting to infamous conduct. They found the facts concerning the signing of blank prescription forms proved, but these also did not in their judgment amount to infamous conduct. The president admonished Dr. Dan De Kar to reconsider his position in regard to these operations, and said that the council took a grave view of laxity in certification.

MOTORING AND DRINK

Patrick O'Neill, registered as of Drombanna, Limerick, M.B. N.U.I. (1939), appeared in consequence of convictions before magistrates in 1943 for driving a motor-car while drunk and for improper use of fuel, and a conviction at assizes in 1946 for dangerous driving, for which he was imprisoned for three months. The council found the convictions proved but dismissed the case.

William Belton, registered as of 39, Blakehall Road, Wanstead, London, E.11, M.B. N.U.I. (1921), appeared in consequence of a conviction at Bow Street in 1938 for being drunk and disorderly and another at Stratford Court House last January for being drunk in charge of a car and for careless driving; he had asked the council also to take account of his dismissal from the Army in 1942 by court-martial for drunkenness and insulting behaviour. Mr. Oswald Hempson, who accompanied him on behalf of the Medical Defence Union, said he had a large practice and was strictly abstemious at home and in working hours. He was easily affected by drink and recognised that he should never touch it. He gave an unconditional undertaking to abstain in future. The council suspended judgment for one year.

James Anderson Edward, registered as of 179, Elm Grove, Southsea, Hants, M.R.C.S. (1929), had been convicted twice last year of drunkenness in charge of a car. He had been summoned to the November session, 1946, but had been at sea. Mr. H. D. Peacock, counsel, instructed for the London and Counties Medical Protection Society by Messrs. Le Brasseur and Oakley, solicitors, said that the doctor was still at sea, working as a ship's surgeon. He intended never to do general practice again, had sold his car, and expressed his apologies and regrets. His fault had been due to grave domestic and financial trouble. The president emphasised the necessity for his appearance before the council in May, 1948, until which session judgment was postponed.

The British Pharmacopœia

Prof. J. A. GUNN presented the report of the Pharmacopœia Committee. This stated that the appendices on tests, assays, and analytical methods had been completed. Comments from the Dominions had been carefully considered in the final revision of the Pharmacopœia monographs. The sections relating to penicillin had been reviewed in consultation with the Ministries of Health and Supply and the makers. The committee recognised that the descriptions of penicillin and its preparations were likely to need revision and extension in the near future in accordance with the rapid advance of knowledge in this field, also that other antibiotics might call for description in the Pharmacopœia.

The new United States Pharmacopœia was published on April 1. In revising the *B.P.* the Pharmacopœia Commission had had the page proofs of the *U.S.P.* at its disposal and had made every effort to bring the two into agreement. It acknowledged with gratitude the longstanding coöperation of the Committee of Revision of the *U.S.P.* The whole *B.P.* was now available in galley proof, but delays in printing and binding made it impossible yet to give a date for publication.

The *Medico-Legal and Criminological Review* is changing its title to the *Medico-Legal Journal* to make it clear that it is mainly concerned with the publication of original material.

Medicine and the Law

The Uncounted Swab

A RECENT inquest at Scunthorpe indicated that death was caused by a swab remaining in the patient's body after an operation. As reported in the *Yorkshire Post* of May 17, the deceased woman had been admitted to a maternity home last February for a cæsarean operation. She was discharged on April 19, but was readmitted $2^1/_2$ hours later and died early next morning from acute peritonitis. A swab was found in the peritoneal cavity. The coroner accepted the evidence of the county pathologist that, when the patient was discharged, there was no reason to anticipate the sudden relapse which followed; peritonitis would be swift in its onset and severe. The coroner considered that the post-mortem evidence showed that no fault could be found with the operation itself or with the care taken of the patient. A verdict of "death by misadventure" was recorded. In the course of his summing-up the coroner commented that there had been an oversight on the part of the sister. He added that the surgeon who performed the operation must bear some part of the responsibility for the sister's lack of precaution, because the counting of dressings was an essential feature of an operation. This last statement is open to challenge.

Nurses are nowadays accepted, as Lord Greene suggested in 1942 in Gold *v.* Essex County Council, as skilled members of a hospital's staff, along with medical practitioners. Nurses are not mere automatons who carry out blindly the directions of a surgeon or doctor. From what Lord Justice Goddard (now Lord Goddard, L.C.J.) remarked in the Gold case, it may be inferred to be possible that a nurse could be regarded as negligent even though she were carrying out the orders of a surgeon. "If a doctor in a moment of carelessness, perhaps by the use of a wrong symbol in a prescription, orders a dose which to an experienced ward sister was obviously incorrect and dangerous, I think it might well be held to be negligence if she administered it without obtaining confirmation from the doctor or higher authority." Lord Goddard conceded that, in the stress of an operation, the first thing required of a nurse would be an unhesitating obedience to the orders of the surgeon.

A study of these and other judicial dicta may lead to some confusion. Lord Justice Kennedy's judgment in the famous case of Hillyer *v.* Governors of St. Bartholomew's Hospital (in 1909) has lost much of its former importance. The courts no longer suggest that in the operating-theatre the nurse is the servant of the surgeon. If she does exactly what he tells her, she will not be found guilty of negligence; if she does something else, it may be otherwise.

To return to the responsibility for counting swabs, is it not the accepted and proper modern practice for the surgeon to leave this to a sister known to be competent? Is he not entitled to rely, in matters within their competence, upon his trained technical assistants? Is not a theatre sister perfectly capable of counting swabs, and is it not clearly regarded today as her duty? If these questions can be answered in the affirmative, does not the comment of the coroner at the Scunthorpe inquest need qualification?

When the Departmental Committee on Coroners (over which Lord Wright presided) reported in 1936, it made some reference to the occasional practice of praise or blame being awarded at inquests in matters of professional treatment. Mr. (now Sir Herbert) Eason, with representatives of the British Medical Association, had drawn the committee's attention to cases where coroners had sometimes censured or criticised hospital staffs and practitioners. Persons so attacked had no redress or remedy; the comments, being made in a judicial proceeding, were privileged and protected, and there was no form of appeal. The committee thought it undesirable that an individual should find himself thus exposed to public censure without the chance of reply. The Wright report, however, made an exception in favour of riders or recommendations of a general character, designed to prevent further fatalities. The lesson of the Scunthorpe inquest, where the conduct of the proceedings was otherwise unexceptionable, may be accepted in that spirit.

Public Health

Smallpox

CONTACTS are still under surveillance in connexion with the outbreaks at Barnsley, Yorks, and Bilston and Coseley, Staffs. A case, the first in the town, was detected at Wakefield on June 4.

Barnsley.—The total of cases is now 15 (with 3 deaths in persons aged 75, 72, and 70). Of these, 9 were in the second generation, and 1 is probably in the third generation. The common lodging-house where the disease first appeared, and its occupants, have been disinfected terminally, but remain under surveillance; the last case, removed on June 4, was in a man who had refused vaccination until June 3. St. Helen's Hospital, from which the last case was removed on May 29, is now empty. Patients and staff from the affected ward have been transferred to the infectious diseases hospital. Other patients have been discharged home under surveillance.

Bilston.—Recently 2 further cases have been reported. The 4th member of the family mentioned last week was removed on June 2. She is 12 years of age, vaccinated in infancy and revaccinated unsuccessfully on May 17, the day after her sister died. Further revaccination on May 23 gave a good take, but she developed modified smallpox rash on June 2 and was removed to hospital immediately. Her mother—another case in the same generation, with onset on May 29—died on June 5. The 2nd patient is a teacher at Villier School, aged 39, vaccinated in infancy and removed on June 4 (onset June 1, rash June 4).

Coseley.—There have been no further cases in this district. Contacts in two households remain under surveillance, and further cases, if any, should crop during the present week.

Wakefield.—This is the only new focus of the disease during the past week. Here a man, aged 71, vaccinated in infancy, became ill on May 31 and was removed on June 4. The date of rash is uncertain, but the clinical state suggests that it appeared about June 2. The man, one of forty-five permanent residents in the Model Lodging House, 62, George Street, Wakefield, was employed as night watchman at the corporation's electricity works. There is evidence that no casual vagrants stayed at the lodging-house; but passers-by frequently sat with the patient at work during the night.

Sheffield.—The last of 3 cases (in two generations) was removed on May 21. Surveillance of contacts has now ceased and the patients are awaiting discharge.

Infectious Disease in England and Wales

WEEK ENDED MAY 31

Notifications.—Smallpox, 14; scarlet fever, 886; whooping-cough, 1057; diphtheria, 194; paratyphoid, 7; typhoid, 1; measles (excluding rubella), 12,314; pneumonia (primary or influenzal), 512; cerebrospinal fever, 73; poliomyelitis, 18; polioencephalitis, 3; encephalitis lethargica, 3; dysentery, 46; puerperal pyrexia, 116; ophthalmia neonatorum, 56. No case of cholera, plague, or typhus was notified during the week.

Of the smallpox cases, 11 were notified at Barnsley, 2 at Coseley, Staffs, and 1 at Sheffield.

Correction: For the week ended May 24, the number of scarlet-fever cases notified was 982.

Deaths.—In 126 great towns there were no deaths from enteric fever, 1 (0) from scarlet fever, 1 (0) from diphtheria, 10 (2) from measles, 13 (4) from whooping-cough, 64 (3) from diarrhœa and enteritis under two years, and 7 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 273 (corresponding to a rate of 31 per thousand total births), including 32 in London.

In England Now

A Running Commentary by Peripatetic Correspondents

GETTING a driving licence in Switzerland is by no means a simple matter. First you have to apply for a provisional permit which requires a photograph, and because this showed your peripatetic correspondent wearing glasses I was told that I had to submit a certificate that my sight, with glasses, was normal. Two opticians assured me they could not give such a certificate; it had to be signed by an ophthalmologist. Through the good offices of a colleague I eventually made an appointment to visit the ophthalmological clinic of the general hospital, where a charming woman ophthalmological surgeon "gave me the works" on slit-lamp, ophthalmoscope, dark vision, &c. This produced a lengthy letter certifying that my sight was normal with glasses, but that, by law, I must always carry a spare pair in the car. Now I have to pass a driving examination, and, much worse, the poor old 1937 Hillman has to survive a stiff test for road-worthiness, after the expenditure of vast sums for new headlights to conform with the Swiss "dipping" regulations and for insurance with a Swiss company. And with all this, I'm told that the comparable accident-rates are far higher in Switzerland than England.

To those who complain of bureaucracy and form-filling in Socialist England, I suggest they will find this free-enterprise country far worse. And what a sweet racket has been missed by ophthalmologists in Britain!

* * *

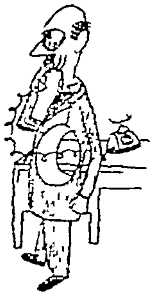
The association meeting finished early, leaving me in a strange town with a couple of hours before my train went. It was a nice afternoon, but of course early closing day, so looking into the shop windows was a sterile pleasure. However, I knew that the town had a pleasant river and I walked towards it, anticipating its coolness that hot summer's day. To my surprise the bridge had a toll-gate: "Passengers are liable to pay 1*d.* for the use of the bridge or road." Very well, I paid my penny and walked on to the centre of the bridge, looking down at the river, the greenery, the red buildings of the school in the background. In a moment a tub pair came along with two boys and a coach. It is more than 20 years since I did any rowing, but the sight of those two boys, doing everything wrong, made me feel like a cat looking through the window at birds on the lawn: I longed to get at them—arms wrong, hands wrong; oh, if I had a megaphone! But they passed underneath the bridge and floated away, happy in their ignorance. I returned the way I had come, to be greeted with "One penny, please." "But I just paid a penny; why should I pay another?" "The rule says you must pay a penny every time you use the bridge." "But I only used the bridge once!" "Well, that's the rule; a penny please." And alas I had to pay, with the poor consolation that next time I could walk on to the bridge, watch tub pairs all the afternoon and walk off again, without paying a penny, as long as I did not pass through the toll-gate. This in 1947!

* * *

More Hints for Doctors' Brides.—If you and the doctor make any rules about messages they will be broken in the first 24 hours. Rules are made for the panel patient but they are not often observed, though things are a lot better than they were before the war. Face the fact that there is no escape—it is useless trying to isolate yourself in the kitchen. Besides the adjustment you are forced to make to marriage you will have to adjust your marriage to the practice. You will have no devastating shock-absorbing receptionist to tell the doctor that two of the patients he most dislikes desire his early attendance. If you are out for half an hour taking the kids to school it will be then that the phone will ring its head off, and you will be greeted on return by an irritated type champing on the doorstep who will be quite unmoved by your information that you have done the shopping in record time.

When the doctor returns for lunch and you have a bagful of fresh messages for him you must be on your best form. You are the nearest object and whatever your form you will catch the blast. Avoid saying anything as if you were anxious about the fate of the messages you give. Bite down the desire to slip in that delightful sentence by C. S. Lewis to the effect that the future is something which everyone reaches at the rate of sixty minutes an hour, whatever he does, whoever he is. Bite off every witty retort you can think of—and you will think of many. Your sense of humour, though it is coupon-free, will be a utility garment oft-repaired and much treasured by the time your marriage is a year old. If there is much sunshine on one of those days when too much is demanded of your husband your reaction will be to cram your hat on your head and rush out into the countryside leaving the whole shooting-match to go to blazes. Rest assured, it will certainly do so. As you reach the end of the drive (garden path, front passage) you will be met by a scared child who says, "Please tell the doctor to come quick! Me mum's bin took bad (fallen down stairs, started 'er pains, cut 'er 'and opening the rations, put 'er 'ead in the gas-oven, &c.)."

Never mind, you will find that things are seldom so urgent as they seem. Always leave the doctor to decide. Never commit yourself. If after a year in the place he seems not to know what is urgent and what can wait a few minutes . . . well, girlie, you've had a tough break. Your most subtle question to the message-bringer is, "How long has he been ill?" (A gentle, innocent tone should be used.) Your careful reportage of the answer will bring you laurels and—who knows—may eventually lead the way to that little shop off Bond Street. Always assist your husband in his dash to the bedside of a perforated company-director (promoter, accountant, foreman, plumber, *grocer*, wine-merchant, &c.):



Perforated company-director

You must be on really palsy-walsy terms with the district nurses. If one rings up briskly, stating that she has a placenta prævia, do not ask, "What is that?" Say, just as briskly, "Harry is not due back until tonight. You had better ring up the hospital straight away. Tell Sister Blank he asked you to. I'll fix it with Harry when he comes in." Nurse will bless you, for you have made up her mind for her. Your husband is far too young to deal with things like that.

Here is a useful tip. When a caller asks for your husband to go to an unknown destination, and the caller is practically a moron, get him or her outside the post office facing uphill (as it were) and then lead them, in imagination, back to their homes, noting prominent places en route (just to check up on them). Remember, of course, that they will not have noticed places like the museum or Lloyds Bank; the public lavatories, the bus park, the Food Office, the Statchew, and the traffic lights will be more useful.

Snippets: Be sweet to the H.P. at the hospital; he has probably rung up to apologise to your husband for erroneously correcting Harry's diagnosis, and he is lonely at night anyway.

Go on and on at Harry to make sure he has not forgotten the message you gave him while he was shaving; his toilet demands immense concentration.

Never expect any thanks for anything from anybody; occasionally someone with a more than average imagination will send you a bunch of flowers; put these in the consulting-room.

In struggling towards a sense of proportion remember that your efforts are worth £90 per annum for income-tax purposes. What more could one desire in this life?

* * *

He was found dead in the kitchen with the gas turned on. He was a single man who had worked hard and had lately been a little worried about making do with his rations. Autopsy revealed a cerebral hæmorrhage, but his old aunt, who was his nearest relative, said she was quite satisfied with the coroner's verdict: "death from national causes."

Letters to the Editor

BACKACHE

SIR,—I wish to congratulate Burns and Young on their magnificent article of May 10. They have done pioneer work in England on this difficult subject, and have also shown great courtesy in explaining and demonstrating their technique to other orthopædic surgeons. A visit to their department at St. George's Hospital on a Thursday morning is most stimulating.

From their article and subsequent letters it appears that, although removal of a damaged disk may become necessary, non-operative measures often give relief—at least for a time. The forms of non-operative treatment recommended are:

(1) Rest in bed for three weeks, followed by the wearing of a corset (Burns and Young). In their hands neither physiotherapy nor epidural injections give lasting benefit.
(2) The wearing of a well-moulded plaster jacket for 2–3 months (Crisp).
(3) Osteopathic manipulations (MacDonald).

At a meeting of the British Orthopædic Association last year Cyriax demonstrated the effect of epidural injections on a recent case of lumbago, and his method of gentle manipulations. Kenneth Stone suggests the possibility of the presence of a rheumatic state either preceding or coincident with a disk injury.

The changes occurring in a torn or prolapsed intervertebral disk are in some respects similar to those seen in a torn internal semilunar cartilage. In the latter the flexors of the knee—the semimembranosus, semitendinosus, sartorius and gracilis—go into spasm. Full extension of the knee is impossible, partly through this spasm and partly through mechanical locking of the joint by the displaced torn piece of meniscus. When a tear is on the periphery, healing may take place if the knee is supported in plaster-of-paris and the muscles are moved isometrically (in contradistinction to isotonic contraction). If the knee is manipulated forcibly under an anæsthetic replacement may take place; but often the damaged cartilage is further contused and little improvement is obtained.

It can be seen that the contusion or tear causes (1) an inflammatory state of the joint, with (2) spasm of the surrounding muscles, which leads to (3) muscle imbalance between the flexor and extensor groups and muscle wasting. Each one of these factors must be treated separately, the first by rest and heat, the second by massage and gentle manipulation, and the third by graduated exercises and faradism.

During the past fifteen years I have had to treat several thousands of cases of low back pain, with or without sciatica. It is my impression that:

(1) In some cases there is a state of tissue œdema, due to transudation of fluid, before the true attack. Copeman and Ackerman [1] suggest that œdema of the tissues, especially the fatty tissues, may occur in fibrositis.

(2) If the disk is torn or if the pulp protrudes, there is inflammation not only round the disk but in the surrounding vertebral articulations. This is one of the causes of limitation of movement.

(3) The muscles of one side go into protective spasm, and the spasm accounts for the posture and for sciatic scoliosis, either homolateral, heterolateral, or alternating. The result in course of time is contracture of one group of muscles (with loss of extensibility), overstretching of the opposite group, muscle wasting, and all that goes to make for muscle imbalance. It was in such cases perhaps that successes were obtained in the past with forcible manipulation in the later stages, when the disk may have slipped back.

(4) With faulty posture—e.g., in a person with a marked lordosis and a pendulous abdomen, or in a man sitting in a cramped position in a tank—there is loss of *synergic action* between the spinal extensors and flexors; the front of the vertebral bodies are subjected to undue pressure and there is a tendency for the intervertebral disk to be squeezed backwards. Balanced synergic action between these groups must be restored by appropriate pelvic tilting exercises, so that the spine is straightened and the abdominal muscles are contracted and elevated and the buttock muscles *tighte* i.e., stand as if sitting on a shooting-stick.

(5) Tender points occur in relation to the sacro-iliac joint; either at the origin of the glutei or in the insertion of erector spinæ. Sacro-iliac tests are usually found to negative. It is suggested that these tender areas are the result of *primary muscle strain of the glutei* or erector or the result of muscle spasm in cases of lumbago or sciatica (cf. tennis elbow).

Young [2] describes two types of disks. In cases of prolapsed disk, giving rise to the compression syndrome, side bending *towards* the lesion is painful. In cases of tear of the annulus fibrosus, giving rise to a stretch syndrome, side bending *away* from the lesion is painful. This does not tally with Burns and Young, who state that sideways bending is free. I have found cases vary with regard to side bending; but where there is pain away from the lesion (stretch type, annulus tear) the condition might heal completely if the back was rested in a plaster jacket for three months.

I suggest that cases should be placed in the following groups:

1. *First attack, or patients refusing operation.*—Treatment is directed to reducing inflammation, muscle spasm, and (if possible) prolapse. The patient lies prone on two pillows supporting the abdomen, his legs being supported by further pillows to flex the knees slightly. Each day he is given infra-red heat for ten minutes, friction massage for ten minutes, gentle faradism to the erector spinæ and glutei for ten minutes, and anodal galvanism for ten minutes. We have had patients in severe pain coming in with a pronounced sciatic scoliosis, verified by X rays, and after the first treatment this has disappeared clinically and radiologically. The treatment must never be stimulating. If more than a subthermal dose of diathermy is given the symptoms are often made worse, and for this reason diathermy is not advised, especially in the early stages. If there is improvement gentle manipulation is added.

The patient is told to rest as much as possible, but back is supported by a felt pad and elastic webbing (a simple and practical method of giving support quickly, for of a corset, made to measure, takes weeks to obtain). In many cases he is almost symptom-free within a few days, and a great deal of time has thus been saved. Some patients experien a feeling as if something has slipped back into position. A few have shown no improvement, and at the end of a week treatment have either been given three weeks' rest in bed using bedpans, or, when this was impossible, have been giv a plaster jacket.

2. *Annulus fibrosus tears.*—A plaster jacket for t months, with operation if there is aggravation at first recurrence later. Recently we have had to operate on a patient, who had complete freedom from pain for eight months after wearing a plaster jacket for four months. At operation a large prolapsed disk was removed.

3. *Patients over 45 showing spinal arthritis with disk prolapse.*—Treatment should be as in group 1 and must be given a long and thorough trial before deciding on operation, *since this type of case may require spinal grafting* as well.

All patients have pelvic tilting exercises, and many have told me that if they have felt pain in their backs and carried out these exercises at once the pain has disappeared in a short time.

London, W.1. W. E. TUCKER.

ON THE RECORD

SIR,—Readers of your leader of May 24 may also like to hear that during the past year discussions have taken place among a group of provincial hospital records officers as to how the many problems of their departments could be eased immediately and solved eventually. It is recognised that the standard of clinical records is primarily a medical responsibility, but this responsibility could be lightened, and time and expense saved, by the provision of trained lay assistants. America and Canada long ago recognised that this section of hospital administration was a specialty, and organised training in these two countries has achieved its objects. The standard of records is said to be good, and experienced staff are available for the work.

---

[1] Copeman, W. S. C., Ackerman, W. L. *Quart. J. Med.* 1944, 13, 37.

[2] Young, J. H. *Med. J. Aust.* 1945, ii, 234.

Records officers are attempting to improve standards th of the records and of the organisation of these partments, but their efforts are hampered by transient d often unsuitable staff, combined with lack of appreciaon of the importance of their work in service to the ck. Meetings have been held at the Christie Hospital, anchester, to ascertain the possibilities of following merica's example. It is thought that the best first eps would be the inauguration of:

Schools in university teaching hospitals for lectures and practical training.

A two years' course, with issue of diploma or certificate to students passing the examination.

An examining board with medical, administrative, and records-officer representation.

An association of qualified records officers.

Several of the provincial university hospitals houseovernors and superintendents have approved the cheme in principle. The support of other official odies concerned with medical records is being sought, nd I will gladly give further information to anyone nterested.

Elsie Royle
Christie Hospital, Withington, Manchester. Records Officer.

MULTIPLE-PRESSURE VACCINATION

Sir,—I should like to express my agreement with the etter by Dr. Vaughan in your issue of May 24. In a airly extensive experience of the multiple-pressure method of vaccination I found it to be much more eliable than the scratch method. I first used this method in 1943 when I was responsible for the health of large numbers of recruits to the Nigerian Forces. I was dealing with an intake of 600–800 men a month. About two-thirds of these men had been vaccinated by civilian African medical orderlies, using the scratch method, one to three weeks before they reached me, but in a large proportion—certainly over 50%—this vaccination had been unsuccessful. Revaccination of these men, and vaccination of recruits not previously vaccinated, using the scratch method, gave little better results. After changing over to the multiple-pressure method, however, failures became relatively very few. In all cases lanolated sheep lymph was used.

A further test of the method was given when a small outbreak of smallpox occurred in the camp. All ranks who could not show a very recently healed vaccination scar were revaccinated, this being the only effective way to ensure that none was missed. About 1000 men were vaccinated or revaccinated and less than 100 of these failed to develop a reaction. At a second attempt almost all the failures were successfully vaccinated.

Like Dr. Vaughan, I have in several cases obtained well-marked reactions in Europeans who have been repeatedly vaccinated in the past, including one N.C.O. who had been unsuccessfully vaccinated by the scratch method 6 or 7 times in the previous three years. He had not been successfully vaccinated since childhood. Vaccination by the multiple-pressure method was almost embarrassingly successful in this case, resulting in a very severe reaction of primary type necessitating some days in hospital. In the minimal reactions, as Dr. Vaughan has stated, itching was a most characteristic symptom.

The multiple-pressure method had the further advantage that I was easily able to teach my Nigerian orderlies to perform it correctly, which I had completely failed to do for the scratch method—probably explaining the bad results. As Dr. Vaughan remarks, the skin in the Tropics is hyperæmic, and in many Africans it seemed to be very easily pierced, so that the "scratch" produced by an orderly nearly always drew blood. Indeed some recruits, vaccinated elsewhere, reached my M.I. room with what were to all intents and purposes septic gashes.

The multiple-pressure technique is very easily acquired, needing only a few minutes' practice, and it is as quick as, or quicker than, the scratch method, done properly, because there is not the same need for carefully testing and varying pressure, according to the thickness of the individual skin; it soon becomes a purely automatic action.

Caerleon. W. C. D. Lovett.

HÆMOLYTIC DISEASE OF THE NEWBORN

Sir,—In answer to Dr. Henry Third's question (May 31) as to whether I would suggest that the "logical treatment of a severe case of icterus gravis, where . . . there is no anæmia, is to transfuse with Rh-negative blood 'to correct the anæmia,'" I would reply that if there were no anæmia to correct there would be no need for a transfusion.

If the title of "hæmolytic disease of the newborn" is to be changed at all, it should not be changed, as Dr. Third suggests, to "rhesus disease of the newborn," but to the more correct title of "iso-immunisation disease of the fœtus and the newborn"—if for no other reason than that "rhesus" is the name of a species of monkey!

Birmingham. Leonard G. Parsons.

ESTIMATION OF VITAMIN C IN LEUCOCYTES

Sir,—The hydrazine method for the estimation of vitamin C in leucocytes, described by Dr. Constantinides in your issue of May 31 (p. 750), purports to be a modification and an adaptation to a micro procedure of Roe's method. Unfortunately the author has not referred to the relevant work on the subject of his paper, apart from that of Butler and Cushman.[1]

To our knowledge, Roe's method has been used on leucocytes in various parts of the world by a variety of workers over several years. One of us (B. B. L.) started using it thus in 1943, shortly after the publication by Roe and Kuether[2]; our method, which has been published in *Recent Advances in Clinical Pathology* (p. 187), and Dr. Constantinides's method are almost identical. We use 3–20 ml. of blood, yielding 10–200 mg. of leucocyte-platelet layer. Dr. Constantinides uses 15 ml. and calls his method a micro procedure. It is quite unnecessary to use such large amounts of blood: Lowry et al.[3] have reported results for the leucocytes and platelets in 0·1 ml.—i.e., 1/150 of the amount that Dr. Constantinides uses in his "micro procedure." There is no published evidence for Dr. Constantinides's statement that "the interference of -SH groups such as glutathione" occurs in the estimation of ascorbic acid in leucocytes by the indophenol method (cf. Butler and Cushman [1]). Dr. Constantinides states that the hydrazine method is "extremely sensitive and specific." But there is published evidence[2, 4] that some reducing substances which interfere in the indophenol method also interfere in the hydrazine method. Having examined possible interference by substances other than ascorbic acid present in blood, Roe recommended the use of a filter with maximal transmission at 5400 Å, knowing that the absorption maximum of the pure ascorbic-acid derivative was at 5200 Å. Until it has been shown that the increased absorption at 5200 Å is wholly attributable to ascorbic acid it seems desirable to follow Roe's recommendation, as we have done. Apart from this, and the introduction by Dr. Constantinides of an error of the order of 5% by ignoring the volume of the leucocyte-platelet layer in his calculation, his method is practically the same as the method we have been using.

Dr. Constantinides says that "The ascorbic-acid content of leucocytes estimated by the hydrazine method agrees with the values given by the indophenol method." He quotes no evidence in support of this, and as he gives results for estimations by one method on only 8 samples it is reasonable to doubt if he has obtained such evidence; the fact that his range for 7 healthy persons overlaps the range obtained by Butler and Cushman by the other method is not evidence. However, we published two years ago[5] some remarks about the estimation of ascorbic acid in the leucocyte-platelet layer by the hydrazine method, and included a correlation between results obtained by the hydrazine and indophenol methods on 89 human samples.

Finally, Dr. Constantinides suggests that the lower mean value (29 mg.) which he gets on 7 healthy subjects, when compared with the mean value of 34 mg. which

1. Butler, A. M., Cushman, M. *J. clin. Invest.* 1940, 19, 459.
2. Roe, J. H., Kuether, C. A. *J. biol. Chem.* 1943, 147, 399.
3. Lowry, O. H., Bessey, O. A., Brock, M. J., Lopez, J. A. *Ibid*, 1946, 166, 111.
4. Roe, J. H., Oesterling, M. J. *Ibid*, 1944, 152, 511.
5. Lloyd, B. B., Sinclair, H. M., Webster, G. R. *Biochem. J.* 1945, 39, 17.

Butler and Cushman obtained by a different method, may "reflect the difference in nutritional level between the post-war British and the pre-war American populations." This is quite unwarranted. It would be much less unsound to compare Dr. Constantinides's mean of 29 mg. (on only 7 subjects) with the means of 24·2 ± 0·6 mg. ($n=27$) or 23·7 ± 0·6 mg. ($n=27$) which Lowry et al.[3] obtained by the same method[6] on two groups of R.C.A.F. personnel who daily received respectively 70 mg. of synthetic ascorbic acid and an average of 78 mg. from their rations; if this comparison is made would one not conclude that the post-war British diet contains more than 78 mg. daily—which would satisfy even the most vigorous ascorbic-acid gluttons? Our mean for ascorbic acid in the leucocyte-platelet layer of 1351 samples from British subjects examined by the hydrazine method during the war was 14·0 mg. per 100 g.

CLICKING PNEUMOTHORAX

Sir,—Dr. Thomson describes in his paper of May 10 curious sounds synchronous with the heart-beat audible at some distance from the patient. He thinks the sounds are probably due to a small (spontaneous) left-sided pneumothorax in contact with a pleural adhesion, and he notes that they disappear when the pneumothorax enlarges. In two patients of mine a left artificial pneumothorax had been successfully induced for pulmonary tuberculosis. Refills regularly given formed a good pneumothorax as shown radiologically. Some adhesions were present in the upper zone. It was not until after about six months' treatment that the patients reported "funny noises" of the type described by Dr. Thomson. The noises were not permanent, but I and some other doctors heard them at a distance of about two feet. The patients felt absolutely well and were only somewhat annoyed that the noises sometimes prevented them from falling asleep.

Dr. Thomson's explanation may be correct, though an alternative one is possible. It seems unlikely that the cause of the manifestations is situated in the pneumothorax. If it were they should be more common, whereas in fact not many physicians have met with an example. The sounds may arise in the pericardial sac, if some air from the pneumothorax enters it through a gap formed when adhesions between the pericardium and pleura are torn. In the pericardial sac some fluid is produced in the same way as in pneumothorax. At every beat the heart then hits the fluid in the hydropneumopericardium and produces the sounds. The condition might to some extent be compared with hippocratic succussion. It is interesting that Dr. Thomson mentions (case 3) "a sound suggesting pericardial friction."

Hull. L. Dunner.

MODERN CARE OF OLD PEOPLE

Sir,—While welcoming your series of articles, as showing what should be done, I feel that there is a need to mention some of those things which should *not* be done when catering for the elderly.

The most frequent of these sins against the aged is to imagine that "they have had their day, poor dears." I know a number of old folk, some over 80, who are reasonably active, intelligent, and mentally alert. The common practice of putting such patients to bed and keeping them quiet, with sedatives if necessary, cannot be condemned too strongly. As Dr. Marjory Warren has shown, elderly patients are best kept out of bed as much as possible and encouraged to develop interests of their own. The usual excuse of shortage of staff is sheer nonsense. Old people who get up and about need fewer nurses or attendants than those who remain in bed.

The second heresy is the view that there is little response to medical treatment in old age, so that any sort of doctor is good enough. My own experience with Chelsea pensioners suggested that while diagnosis was more difficult than in earlier life, prognosis among aged patients depended to a great degree on starting treatment quickly. Pneumonia, for instance, is no longer "the old man's last friend" in the original sense of the phrase. Taking a different example, it is surprising how an elderly arthritic patient can be rendered mobile with little care and persistence. Similarly, many hemiplegics can be rehabilitated if proper remedial exercises are carried out from the start. Part-time general practitioners or newly qualified medical men are not the proper doctors for the aged. Old folk need more time, greater skill, and more intense interest than young ones. Their tendency to multiple disorders underlines the fact that nobody can know too much to treat these patients. Extensive clinical and pathological investigation may be necessary, considerable therapeutic judgment is often required. But when these are available a surprising dividend will be paid. Tough old folk are not a bad medical investment.

Finally, I would suggest that drab surroundings, limited visiting hours, uncomfortable furniture, and rigid institutional atmosphere are too common in hospitals and homes for the aged. Old men, and still more old women, are made miserable by being cooped in dull barracks. More colour, more comfort, and more freedom and elasticity are overdue. An Austrian physician, Lorand, once recommended life in an English workhouse as a means of attaining longevity. Today, our object should be "to add life to the years, not years to the life."

Purley, Surrey. Trevor H. Howell.

W.H.O. AND GREECE

Sir,—Dr. Judith Waterlow, in her letter on public-health work in Greece published in your issue of May 31, makes certain strictures on the administration, which, in particular cases, may have some foundation.

I must, however, most emphatically deny her very sweeping allegation that "the Greek government will not employ even the humblest clerk if he helped to resist the German occupation." This, of course, is untrue. I myself was in Greece throughout the occupation and can vouch for the fact that a very high percentage of the population, whatever their political affiliations, were engaged in some form of underground resistance against the Italian and German invaders.

It is true that, under present conditions, the Greek government is chary of employing Communists in the public services, even if they took part in the resistance, because so many of them have engaged in disloyal activities against the State since the liberation. But the majority of Greeks are not Communists but just ordinary patriotic citizens—we may call them Nationalists—who played their part in the resistance; and it is as ridiculous as it is unjust to pretend that they are excluded from the public services just because they helped to resist the German occupation.

A. A. Pallis.

Greek Government Department of Information,
34, Hyde Park Square, London, W.2

Sir,—Dr. Waterlow maintains that, because of the Greek government's interference with health work, the money of United Nations taxpayers will be wasted if applied to Greek health reconstruction. She believes that it might more profitably be spent in aiding countries such as Poland and Yugoslavia.

Her reference to Greece as one of "two countries chosen for special missions on the spot," ignores the fact that the World Health Organisation Interim Commission (Whoic) has missions not only in Greece but also in China, Ethiopia, Italy, and Hungary, while others are planned for Yugoslavia (for plastic surgery), Poland, and Austria.

Further, the choice of countries in which field work should be carried out does not rest solely, or even mainly, with the Interim Commission. The agreement with Unrra under which Whoic undertook to continue Unrra's work during 1947, to the extent that the $\$1\tfrac{1}{2}$ million generously provided by Unrra would allow, specifically mentioned the missions in China, Greece, and Ethiopia as worthy of continuation. Much more important, however, was the very natural condition that programmes must be planned in agreement with the governments concerned. Except that Whoic is unable to provide medical supplies, no restrictions whatever were placed on the form of assistance that governments might request. That there are no missions in, say, Czechoslovakia or the Ukraine is simply because the

---

6. Bessey, O. A., Lowry, O. H., Brock, M. J. *J. biol. Chem.* 1947, 168, 197.

governments of those countries have asked for fellowships, medical literature, &c., and not for missions.

That there has been unwarranted political interference with UNRRA's health work in Greece, as elsewhere, no-one can deny. But in most of the cases representations have succeeded in putting matters right—admittedly after exasperating delays. As so often—and again this is not confined to Greece—the original "scandal" has become widely known but the subsequent correction is not "news" and is consequently not disseminated.

Dr. Waterlow states that "the Greek government will not employ even the humblest clerk if he helped to resist the German occupation"; but surely his risk of unemployment does not depend on his resistance to German occupation so much as on his past or present connexion with Left Wing groups—however deplorable such discrimination may be.

That Dr. Waterlow's views on the undesirability of assisting Greek health work are not shared by the majority of her former colleagues in Greece is shown by the many applications from UNRRA and voluntary-society workers there to continue their work under WHOIC auspices—applications which have nearly all had to be refused, as the WHOIC mission in Greece is limited to eight imported staff. Some of these workers, indeed, are continuing there without salary. Finally, a striking testimony to the value which the Greeks attach to outside expert advice is shown by the agreement recently concluded with WHOIC under which the Greek government agree to pay more than half of the costs of the WHOIC mission—no inconsiderable sum.

However, we can all agree that Dr. Waterlow's letter will have served a useful purpose if it has contributed in any way to preventing political interference with health work in any country.

NEVILLE M. GOODMAN
Director, field services, WHOIC, and late director of health, UNRRA, European Regional Office.

Palais des Nations, Geneva.

*** UNRRA's health campaign in Greece was described in these columns a year ago (1946, i, 789) by Dr. J. Miller Vine, who said that despite "multitudinous difficulties" the medical rehabilitation of the country was in full swing. In a paper read at the Royal Society of Medicine on March 28 he further described the success of the campaign against malaria, "the age-old scourge of Greece." Spraying of the marshes by UNRRA aircraft using D.D.T. has given brilliant results.—ED. L.

INFECTION BY INJECTION

SIR,—May I ask: (1) Why it is assumed that water is the only liquid that can be boiled? (2) Cannot bacteriologists tell us the temperature at which spore-bearing organisms will be destroyed? (3) Cannot chemists or physicists tell us of a substance or solution which boils at this temperature? Syringes could then be sterilised by boiling them in this substance or solution.

London, W.1. A. S. BLUNDELL BANKART.

THE OUTLOOK FOR PHYSIOLOGY

SIR,—We have observed that some writers on scientific topics use metaphors to give point, interest, or liveliness to arguments already expressed clearly in technical language; with others, however, the appearance of metaphors in their writings is a sign that principles of doubtful validity are about to be foisted on the reader.

Professor Lovatt Evans's lecture in your issue of Jan. 18 contains at least one metaphor of the second kind. Under the heading "Teaching of Physiology" he says: "It may be that in the very distant future some broad generalisations will emerge, as a result of which all physiological phenomena will be capable of expression in a few mathematical formulæ and chemical equations; but such a final crystallisation could only emerge from a mother-liquor supersaturated with exceedingly abundant and intricate detail." This passage implies that the generalisations of physiology are formed as the final result of reflection upon immense collections of fact, accumulated over long periods and including as much intricate detail, relevant and irrelevant, as the accumulators can discover. If this is so, physiological method differs from that used in other sciences. Almost without exception, the work of the great investigators in other branches of science has not been based upon this principle. Galileo, Newton, Harvey, Dalton, and Pasteur based hypotheses on comparatively few and simple facts, and while validating the hypotheses widened the factual knowledge relevant to the hypotheses, which altered shape as relevant information came forward. It would be extraordinary if, in order to grow, it were necessary for physiology to reject the methods customary in other sciences.

Professor Lovatt Evans's metaphor would apply more easily to a process of intellectual concretion than to intellectual calculus or crystal formation.

C. E. PALMER
Lecturer in Scientific Method.

Department of Physiology, University of Melbourne.

R. DOUGLAS WRIGHT
Professor of Physiology.

ACTION OF CURARE ON THE FŒTUS

SIR,—I have recently had the opportunity of observing the effect of curare on the human fœtus. During an operation for the removal of a large fibromyomatous uterus with a fœtus of 19 weeks, at the suggestion of the anæsthetist, Dr. Lawrence Morris, I injected the umbilical vein with 2·5 mg. of tubocurarine (B.W. CO.). To our surprise the fœtus immediately entered into a tetanic spasm involving the flexor muscles of the limbs, which lasted until its death a few minutes later.

This observation may be of interest to pharmacologists.

London, W.1. ALECK BOURNE.

SOCIAL ASPECTS OF EPILEPSY

SIR,—May I make a few observations from the point of view of a medical "sufferer"? In my own case the episodes have been of sufficient severity to produce incontinence and even quite severe physical injury on occasion, and yet I have been able to hide the fact of their occurrence from most of my acquaintance. The main difficulty in social adaptation is that of finding employment, especially as it is surprising with what prejudice one meets even in most enlightened quarters and when man-power is at its shortest. Fortunately, I have several other, more obvious, physical defects with which to explain my rejection from the Forces, but, of course, one cannot perjure oneself in connexion with life insurances or superannuation schemes, so the right job is often difficult to find even then. One has to be able to take things easily when required and to save money, especially as overwork and worry are certainly to be avoided.

A point which is not often realised is that many of us have what I call a remote, as distinct from an immediate, aura. Thus we can tell if an attack is impending and alter our habits and our drugs accordingly. Thus retention of fluids may be obvious for a few days preceding an attack and is easily noticed by the observant.

However, even to the experienced, a major episode is a most terrifying experience, and I am convinced that this fact militates strongly against the use of the water-pitressin test. Although I am perfectly aware of what is happening to me, the sense of utter frustration and helplessness at the beginning of an episode has never had its terrors dimmed by repetition, and I would never submit voluntarily to any procedure which I knew would bring it on.

ANON.

RUBELLA AND CONGENITAL DEAFNESS

SIR,—A few months ago I was called to see a patient, aged 65 years, suffering from a right hemiplegia of sudden onset. I had seen the man for trivial complaints before, and examination was complicated by his being a deaf-mute. His brother who was present told me that the patient had never been able to hear or speak properly—and added that their mother always insisted it was due to the fact that during the pregnancy she suffered from German measles.

In this case an "old wives' tale" has antedated Gregg's discovery by about sixty years. It makes one wonder whether the unsolved mysteries of medicine could not be more easily solved by listening closely to what our patients and their relatives say, and by studying carefully their habits, histories, and modes of life, than by investigating their biochemistry or experimenting on animals.

London, E.2. HUGH L'ETANG

Parliament

ON THE FLOOR OF THE HOUSE

THE outstanding political event of the week was the announcement by the Prime Minister of the early transfer of the political control of India to the Indian people. This development in the settlement of India's relations with us may have a great influence on the moulding of the future constitution of the United Nations as a world authority. The history of the British Commonwealth shows that free agreement without constraint or force of any kind is stronger as a link between nations than the most strictly drawn treaty of alliance.

The other work of the House has included the third reading of the Industrial Organisation Bill, the Agriculture Bill, and report and second reading of the Companies Bill, while the Lords have tackled Town and Country Planning and the National Service Bill. The legislative drive is still on but the tension is less. "Their Lordships" are somewhat alarmed at the possibility of having to sit until 11 P.M. on Mondays to Thursdays, but no-one has yet raised a protest at this direction of the labour of the Peers.

Sir Stafford Cripps and Mr. Herbert Morrison's insistence on increased production has sounded the note to which national activity must attune itself, and the need to economise in dollars means that we must provide more variety in food from home resources. Can the British garden and allotment produce a still larger proportion of British food during the next year? We may have to organise a drive by the W.V.S. and women's institutes to see that the best use is made of the thousands of tons of fruit that go to waste every year in small garden orchards.

MEDICUS, M.P.

FROM THE PRESS GALLERY

Venereal Disease in the Army

Speaking in the House of Lords on June 3 at the second reading of the National Service Bill, Lord MORAN said that the scientific way of life exaggerated the natural disposition of the man of sense to speak only of what he knows; but in the Bill before them it was difficult to see where the provinces of the soldier, the doctor, the politician, and the economist began and ended. The Government assumed that in order to give the country security they must provide a certain number of men for the Army and that this number could be raised only by conscription. Lord Moran admitted that he would himself support conscription if he were persuaded it was essential for security. But in fact he believed there was little risk of war in the next ten years. The Bill was designed not to give us security in time of war but to furnish us with overseas garrisons, and he was concerned about the medical reasons which made service overseas for conscripts so harmful.

Last September Lord Moran submitted to members of the Cabinet statistics concerning the incidence of venereal disease in the armies of occupation overseas. He hoped that, without the obvious disadvantage of publication, these statistics would be considered in any discussion of conscription. But they had not been considered, and he therefore felt obliged to put the figures before their Lordships' house. He realised he might be criticised for doing so, but the figures were given to him, without any condition, as a member of a small committee which advised the Secretary of State for War on medical matters. He held that, as a member of this committee, he had two responsibilities—to advise the Secretary of State, and to reassure the public that all was well in medical matters in the Army. "And if all is not well—and all is *not* well," added Lord Moran, "then I think it is time to speak up."

In the Army in Japan in September last 228 of every 1000 men had venereal disease.* In Germany the figure was 185; in Austria and Italy 168; and in Burma and Malaya 141. In the Middle East where there was little mixing between the Army and civil population the figure was 31. In the Army at home it was 33—much than the usual rate of about 12.

Lord NATHAN, Minister of Civil Aviation, in to ask Lord Moran from what sources his figures obtained as they were irreconcilable with figures in possession. Lord MORAN replied that the figures given to him in September. They were in print originated from the Army Medical Department. He confirmed that recent figures were substantially the

It was quite clear, in Lord Moran's view, that a from home was the vital factor which led to this incidence. It was also due to boredom. The men had healthy means of distraction. Many led a mechanical with not enough to do, waiting for the time to get The figures lent no support to the Prime Minister's a tive idea that the Army was a university, teac citizenship. Noble Lords might ask whether these meant that the price of keeping an army abroad is that 1 every 6 will get venereal disease. While it was true the times were abnormal in the sense that many men been in the Army for several years and were in a " care" frame of mind, Lord Moran thought that figures supplied an indictment of the conditions which these men were living. The most friendly of the Army must feel that they meant that the conscript's time abroad his experience in the was demoralising. The segregation of young men, the beginning of their life, under these conditions poor preparation for the more serious view of life was so sadly needed at present.

Replying to the debate, Lord NATHAN said he had startled by the figures given by Lord Moran of the inc of venereal disease in the Army. Lord Moran had ently been given the figures in his capacity as a m of the medical advisory council to the War Office, they were of a different order of magnitude from supplied by the War Office to Lord Nathan for period January, 1946, to March, 1947, which were as follows:

U.K. Forces: Highest quarter, 9·6 per 1000; lowest quarter, 5·3 per 1000.

Rhine Army: Highest, 44·6; lowest, 30.

C.M.F.: Highest, 39·5; lowest, 22·8.

M.E.F.: Highest, 9·4; lowest, 4·1.

S.E.A.L.F.: Highest, 37·1; lowest, 31·2.

Lord MORAN interposed to say he was quoting A.M.D.5 Statistics, September, 1946. He was giv the annual rate of cases. If Lord Nathan's figures, whi were quarterly, were multiplied by four the result wo not be very different from the figures Lord Moran h cited.

Lord NATHAN agreed that venereal disease was a serious problem which had to be dealt with promptly and properly, and he assured the House that great attenti was being given to it by the Secretary of State for War, the Adjutant-General, and the Commander-in-Chief in Germany.

QUESTION TIME

The Appointed Day Postponed

On June 9 Mr. VIANT asked the Prime Minister when it was intended to bring the rest of the National Insurance schemes and English and Scottish National Health Service schem into operation.—Mr. ATTLEE replied: The preparatory work necessary to arrange the transition from existing schemes an agencies and to create the organisation to operate the new provisions effectively is very heavy. Considerable progress has been made with these preparations in spite of great difficulties of staff and premises. The various schemes are closely linked up with each other and with proposals for completing the break-up of the poor-law and providing a comprehensive scheme of national assistance standing behind the insurance provisions. The Government consider that there are compelling reasons in favour of bringing all these schemes into operation on the same date. They have reached the conclusion that, by giving high priority to the legislation which it is hoped to introduce next session to complete the break-up of the poor-law, this will be possible. On a consideration of all the factors involved they have decided that the best date for this purpose is July 5, 1948, which coincides with the end of the next contribution year for health, pensions, and unemployment insurance.

---

* Later in the debate Lord Moran explained that his figures represent annual infection-rates. Thus in Japan new cases of venereal disease numbered 228 per 1000 per annum.

Conjoint qualification in 1912. He had only just had time to "bed down" in the medical branch of the Navy when the 1914–18 war began, and it was not long before he was serving as P.M.O. of a light cruiser in the Grand Fleet. He was attracted to surgery and in time became a surgical specialist and the youngest surgeon captain in the Service. In 1937 he was appointed to the charge of the Naval hospital at the Cape of Good Hope till in 1943 he was moved to Plymouth. The following year, with his promotion to the rank of rear-admiral, he became P.M.O. Western Approaches, and in 1946 he was appointed honorary surgeon to the King.

"Mike Whelan knew the Service not only by family tradition but also from the executive and medical aspects," writes L. R., "and this may have been partly why he was liked, admired, and respected by everyone in the Service. But the chief reason was his ebullient, cheerful personality; no-one ever saw him downcast, and even when he had a grouse there was a smile on his lips. A fearless administrator, he said and did what he considered right whatever the consequences. A happy family man, Whelan was seen at his best in his own home. He married rather late and his children were young, but he could be young with them. Indeed his boyishness was always near the surface, wanting to break through even on the more solemn occasions—when you might imagine him reminding himself, come let us be grave, here comes a surgeon rear-admiral! And though his career was so rapid and distinguished he was never, like lesser men, weighed down by weight of office or any sense of importance."

RICHARD CLITHEROW

M.R.C.S., L.M.S.S.A., M.P.S., M.P.

As we announced last week, Dr. Clitherow, M.P., died in London on June 3.

Dick Clitherow (writes a colleague) packed a great deal of adventure into his 45 years. He was born and brought up in Liverpool, and it was as M.P. for the Edge Hill Division of Liverpool that he ended his days. At the age of 17 he emigrated to Canada, and for three years he served in the Canadian Mounted Police, rising to non-commissioned rank. In 1923 he returned to his native city, and for two years he was a member of the Liverpool city police force. On leaving the police force he qualified as a pharmacist, and for three years, from 1927 to 1930, he worked as a chemist and druggist in the United States and Canada. Once more he returned to Liverpool, and he had soon successfully established himself in the retail pharmacy business, with several chemist's shops. But these failed to absorb his energies, and in 1937 he was elected to the Liverpool city council. About this time he decided to study medicine, less with a view to practising than to fitting himself further for public life. As with many of those who undertake examinations later than usual, he found some difficulty in surmounting the hurdles; but he persevered and finally qualified after he had been elected to Parliament.

In 1942 he became an associate member of the Liverpool Fabian Society, and a year later he marked his full conversion to Socialism by crossing the floor of the city council chamber to join the Labour group. Throughout the war he did fine work as deputy chief warden in Edge Hill, and the popularity which he gained then as "the man with the beard" probably helped with his subsequent election success.

As a member of the Liverpool Hospital Committee he took a keen interest in the city's hospital services, which at the time he was seeing from the inside as a medical student.

Clitherow showed signs of developing into an inveterate exam-taker. At the time of his death he was already reading for the Bar and talking of taking the D.P.H. His wife, whom he married in 1930, would sometimes jokingly, and perhaps rather wistfully, complain that there seemed to be no end to his studies. He would rise regularly at 6 for two hours with his textbooks before breakfast. And the long hours in the train between Liverpool and London were always spent in study. He was a passenger on the night trains two or three times a week, for he liked to keep an eye on his businesses even when the House was sitting. And it may have been that this hectic way of living contributed to his early death. An attack of pneumonia during the spell failed to keep him away from the House for long.

As a Parliamentary speaker he was effective, with apt and dramatic turn of phrase. His usual sub was the health service of his native city. As a he was not easy to know. A restless streak marked character; he was seeking after something, he knew quite what. He was shrewd rather than learned, and great determination.

His wife and two sons survive him.

ARTHUR FREDERICK BERNARD SHAW

B.A., M.D. DUBL., F.R.C.P.I., D.P.H.

We have to record that Dr. A. F. Bernard Shaw, professor of pathology in the University of Durham and formerly in the Egyptian University of Cairo, died at Newcastle-on-Tyne on June 3.

The son of Arthur Wellington Bolton Shaw, he was born at Carraig-na-Chattan, co. Dublin, in 1888 and educated at Christ's College, Blackheath, and Trinity College, Dublin, where as a student he was twice awarded the medal of the University Biological Association. He qualified in 1911 and spent the next year as demonstrator in pathology in the university. After taking his D.P.H. in 1912 he was appointed senior assistant M.O.H. for Cardiff. But the 1911–18 war deflected him from a possible career in public health, for after serving in Gallipoli, Sinai, and Palestine, he finally became pathologist to the 69th General Hospital of the Egyptian Expeditionary Force. On his return to civil life he returned also to pathology and became lecturer in the subject in the University of Durham. He held appointment till he took up the Egyptian chair in 1933. For his work during the five years he spent in Cairo he was appointed commander of the Order of the Nile. He returned to Newcastle to his present chair in 1938. On the outbreak of war he was appointed regional adviser in pathology to the E.M.S. He was also a member of the senate of the University of Durham.

J. C. S. writes: "Shaw's work in pathology covered three periods, with a Rockefeller fellowship year at Johns Hopkins in America interposed. The first was as a lecturer in Newcastle, where he came in 1919, from an early training in Trinity College, Dublin, and an experience in pathology during the 1914–18 war. His second period was in 1933–38 as professor of pathology in the Egyptian University at Cairo; and the last was again at Newcastle, where he held the chair until his death. In his earlier period, at a time when he was impatiently busy with research, he worked under a burden of routine and teaching, and in physical circumstances so detrimental that they are horrid to look back upon. In spite of the interruptions of illness he completed work, which was widely noticed, on the influence of the vasomotor action on the leucocytic count of peripheral blood, on the diurnal tides of the leucocytes in man, and on constitutional abnormalities of the leucocyte. In addition he added to our knowledge of the pathology of rheumatic fever, and of Riedl's thyroiditis, in articles which are still standard references. In Cairo he had scope for the first time to create a department nearer to his desire. This he did in a way which was a testimony to his powers of organisation and his originality, and he left it a monument to his efficiency and sense of justice, for which the Egyptian government honoured him. In Egypt he made a notable contribution to the pathogenesis of pulmonary schistosomiasis and to the pathology of the spleen, but he was quickly absorbed in reviving the study of palæopathology with new techniques. Here also he found an outlet for his lifelong interest in anthropology and the history of civilisations, and some of his most memorable lectures are those in which he used his study and experience of the Egyptian civilisation to illustrate his views on pathology and the course of civilised life.

"Shaw returned to Newcastle as professor of pathology in 1938. The war was quickly on us but in spite of difficulties he was able to infuse activity into builders and architects to commence a building which would become an institute of pathology within the grounds of the Royal Victoria Infirmary, where pathological anatomy, experimental pathology, biochemistry, and bacteriology would have their place. This was another fruitful period of his life in spite of the inclemencies of war and interruptions of illness. His teaching and his influence then reached their full maturity.

"The nobility of his character and the depth of his mind will be known only to those whom he taught or with whom he was intimate, for he was a reserved man given much to quiet meditation. His was indeed the most cultured mind of any I have known. He had a stern but noble countenance covering a modesty which was at times embarrassing. Deeper still lay a generosity of heart and warmth of feeling which were revealed in a smile of great charm and in acts of exquisite courtesy. He loathed self seeking and insincerity, and was suspicious of Anglo-Saxon compromise. In æsthetics he was relatively insensitive to the visual arts, but vividly sensitive to the form and function of words. There is little wonder that his lectures were unforgetable. They were precise, sincere, and eloquent, with the right and unusual word always coming to his aid. He saw his pathology as part of man's whole struggle with his environment, but would at times laughingly confess that many of its evidences came near to metaphysics. Devoted to the scientific method and poignantly concerned about the function of the university in the modern world, he was intolerant of the compromises which would link commercial and professional interests to a university department, and was anxious to rid the teaching hospital of those burdens and arrangements which prevented it from doing its proper work. It appeared to him logical that a teaching hospital, with the functions of conserving knowledge, of advancing knowledge, and of setting the highest standards of practice should be arranged, administered, and staffed entirely for those purposes, and he saw the solution of this only by making these institutions university departments in the true sense of the word. He could argue these things with fervour, but would cease from arguing at the first sight of fixed prejudice or blind ignorance.

"Uncompromising in his conception of good and evil, of truth and untruth, he may have appeared obstinate at times; but the tragedies of the modern world saddened him, and he saw no way out except by combining reason with science and with that experience of things which we call culture. He lived as near to his own high conception of life as any man could. How strict and distinctive that conception was is known to his friends. By that he will be judged and remembered."

Professor Shaw married Miss Gertrude Frimston, of Liverpool, and they had two sons.

Births, Marriages, and Deaths

BIRTHS

Chippindale.—On June 1, Dr. Ruth Chippindale (née Stevenson), wife of Mr. D. Keith Chippindale, of Trammere Park, Guiseley—a son.

Jenkins.—On June 1, the wife of Dr. Rees Jenkins, of Twyford—a son.

Krauss.—On May 28, at Newcastle-on-Tyne, the wife of Dr. Stephen Krauss—a son.

Logan.—On June 2, at Wilmslow, Cheshire, the wife of Dr. R. F. L. Logan—a son.

Roth.—On May 25, in London, the wife of Dr. Martin Roth—a daughter.

Simmons.—On May 28, at Oxford, the wife of Dr. C. A. Simmons—a daughter.

MARRIAGES

Denham—Colchester.—On May 31, at Pyrford, Surrey, Robin Arthur Denham, M.R.C.S., to Rosemary Henrietta Colchester.

Fawcett—Whiting.—On June 2, in London, James Fawcett, M.B., to Barbara Whiting.

Hadley—Stewart.—On June 7, at South Hinksey, Oxford, George Dickinson Hadley, M.D., to Jean Elinor Stewart.

Joule—Mittell.—On June 2, at Sutton, John Wilfrid Joule, M.D., M.R.C.P., to Mary Louise Mittell, M.B., M.R.C.P.

Petro—Fitt.—On June 4, in London, John Petro, M.B., to Mary Fitt.

DEATHS

Aldridge.—On June 1, at Camberley, Arthur Russell Aldridge, C.B., C.S.I., C.M.G., M.B. Edin., lieut.-colonel R.A.M.C. retd., aged 82.

Allan.—On June 3, at Roehampton, William Smith Allan, M.B. Glasg.

Cato.—On May 31, at Lowestoft, Charles Stanley Cato, M.R.C.S.

Clitherow.—On June 3, in Liverpool, Richard Clitherow, M.R.C.S., M.P., aged 45.

Ewens.—On May 29, at Lowestoft, Bernard Ewens, M.R.C.S.

James.—On June 6, in London, Coram James, M.R.C.S., aged 84.

Morris.—On June 1, in Glasgow, Noah Morris, M.D. Glasg., F.R.C.P.

Shaw.—On June 3, at Newcastle-on-Tyne, Arthur Frederick Bernard Shaw, M.D. Dubl., F.R.C.P.I., aged 53.

Notes and News

EVAPORATED MILK FOR INFANT FEEDING

Unsweetened evaporated milk is now on points, but supplies for infant feeding can be obtained without surrendering points coupons on a doctor's certificate. The doctor should give the mother a certificate stating that the infant is under the age of 12 months and urgently requires evaporated milk. The mother must then take this certificate to her food office, who will issue her with an authority to purchase a month's supply of milk free of points. At the end of this initial month, continued supplies will be authorised by the food office when they receive a further medical certificate. This must give full details of the infant's condition, age, and weight at birth and at application, and must state whether any other milk preparations have been tried and found unsuitable. The following amounts of milk will be authorised under this scheme:

Age of Infant	*Tins of Evaporated Milk*
Under 5 months	Up to 20 tins per 4 weeks
5– 6 „	„ „ 24 „ „ „ „
7– 9 „	„ „ 26 „ „ „ „
10–12 „	„ „ 28 „ „ „ „

University of Oxford

The Nuffield Foundation has made a grant to the university of £50,000, over a period of ten years, to meet the capital and maintenance costs of a hæmatological research unit. The new unit is to be set up in the medical school in conjunction with the Nuffield department of clinical medicine and the Radcliffe department of pathology.

University of Cambridge

Status of women.—The syndicate appointed last January to consider the status of women in the university has now reported. It recommends that women should be admitted to the university and to all degrees on the same terms as men, and that women should be eligible for all emoluments and all offices (except those of proctor and esquire bedell), and for membership of all bodies concerned with the government of the university. Members of the syndicate differ as to the maximum total number of women students *in statu pupillari* which would be desirable, but they are agreed in considering that in normal times it should not exceed a fifth of the total number of men students.

Royal College of Physicians of Ireland

At a meeting of the college held on June 6, Dr. Eamonn de Valera and Dr. J. Browne Fleming were admitted to the fellowship. The following were also admitted to the membership:

Dr. P. M. Alston, Dr. Leslie Doyle, Dr. Leslie Fridjohn, Dr. A. P. Grant, Dr. George Gregg, Dr. John Hayes, Dr. P. D. J. Holland, Dr. W. D. Hughes, Dr. S. D. McGrath, Dr. Harry O'Flanagan, Dr. Bethel E. R. Solomons.

Royal College of Obstetricians and Gynæcologists

On Friday, July 4, at 3 P.M., at the college, 58, Queen Anne Street, London, W.1, Prof. F. J. Browne will deliver the William Meredith Fletcher Shaw memorial lecture on Hypertension in Pregnancy. At 5 P.M. on the same day Mr. J. A. Stallworthy will deliver the biennial scholarship lecture. He has chosen as his subject Fact and Fantasy in the Study of Female Sterility Admission is by ticket, which may be had from the secretary of the college.

Faculty of Radiologists

The annual meeting of the faculty is to be held in Birmingham from Thursday, June 26, to Saturday, June 28. The speakers will include Prof. Robley Evans, of the Massachusetts Institute of Technology, and Dr. J. Hamilton, of the Radiation Laboratory, Berkeley, California, who will discuss the Therapeutic Uses of Radioactive Isotopes. Dr. Brian Taylor, Dr. T. Lodge, Mr. A. L. d'Abreu, Mr. C. J. L. Thurgar, and Dr. Peter Kerley will open a discussion on Carcinoma of the Bronchus. At the therapy section Prof. B. W. Windeyer, Dr. P. B. Mumford, Dr. Bernard Tate, and Dr. J. F. Bromley will speak on Organisation for Superficial X-ray Therapy, and at the diagnosis section Prof. J. M. Smellie, Dr. J. C. Bishop, and Mr. H. H. Sampson on Bronchiectasis in Children.

Royal Society of Tropical Medicine and Hygiene

At the annual general meeting of the society to be held at 26, Portland Place, London, W.1, on Thursday, June 19, at 8 P.M., the new president, Sir Philip Manson-Bahr, will be inducted.

Pharmaceutical Society of Great Britain

Mrs. Jean Kennedy Irvine has been elected president of the society. Mrs. Irvine is superintendent of the Ministry of Health's south-eastern pricing office.

Manchester and District Medical Golfers' Assocation

The silver challenge cup of the association was won on June 4 by Dr. J. McSorley. There were 92 competitors.

Royal Institute of Public Health and Hygiene

The Bengué lecture is to be delivered at the institute on Thursday, July 17, at 3 P.M., by Dr. I. W. Magill, who will give a Review of Modern Anæsthesia.

Congress on Mental Health

The international congress which is being arranged by the National Association of Mental Health will be held at the Central Hall, Westminster, from August 12 to 21, 1948 (not this year, as announced in our issue of May 31).

Brighton and Sussex Medico-Chirurgical Society

Mr. H. J. McCurrich, the president, took the chair at the centenary dinner of the society on June 5, when the guests included Lord Moran, Sir Alfred Webb-Johnson, the Bishop of Lewes, and the Mayor of Brighton.

Fees Payable by Local Authorities

As an interim measure and without prejudice to subsequent negotiations, the Minister of Education has accepted the scale of fees for sessional or occasional work by doctors approved last February by the associations of local authorities and the British Medical Association (*Lancet*, March 29, p. 432).

Surgical Rubber Gloves

Doctors who need surgical rubber gloves for professional use are reminded that they should apply to the secretary of the Central Medical War Committee, B.M.A. House, Tavistock Square, London, W.C.1, marking the envelope "Gloves" in the top left-hand corner, and enclosing a stamped addressed envelope for reply. They will then receive a booklet of six certificates.

Records for the New Service

The Minister of Health has been advised that the executive councils which, under the National Health Service Act, will organise the local family-doctor services will need two registers—a nominal register, in alphabetical order, of persons who have been accepted by doctors, and a medical register. The existing records of the insurance committees, reorganised in alphabetical order, will form the nucleus of these new registers, and Mr. Bevan has accordingly asked the committees to help in the preparatory work by checking and bringing up to date their records of insured persons.

Maternity and Child Welfare Conference

The National Association of Maternity and Child Welfare Centres is holding an international conference at Friends House, Euston Road, London, N.W.1, from June 25 to 27, on the Present and Future of Maternity and Child Welfare in Europe. The speakers will include Dr. J. Greenwood Wilson, Dr. Fraser Brockington, Sir Allen Daley, Sir Andrew Davidson, Dr. H. E. Magee, Mr. Ian Sutherland, and Dr. Frederick Heaf. Mr. Aneurin Bevan, the Minister of Health, will open the conference with his presidential address at 10.15 A.M. on Wednesday, 25th.

Montreal General Hospital

Mr. J. H. Quastel, D.SC., F.R.S., has been appointed director of the enzyme research division of the Institute of Special Research and Cell Metabolism lately set up at Montreal General Hospital. McGill University has simultaneously appointed him to a professorship in the department of biochemistry, whose chairman is Prof. D. L. Thomson.

Before taking up his present appointment as director of the Agricultural Research Council's unit of soil metabolism, Dr. Quastel was director of research at Cardiff City Mental Hospital, and he has published many papers on bacterial biochemistry, on the metabolism of the fatty acids, and especially on the biochemistry and pharmacology of the central nervous system. He expects to sail for Canada in August.

Diary of the Week

JUNE 15 TO 21

Sunday, 15th

Empire Rheumatism Council
10 A.M. (Apothecaries' Hall, Blackfriars Lane, E.C.4.) Dr. F. Cooksey: Physical Treatment in the Rheumatic
11.15 A.M. Mr. W. D. Coltart: Orthopædic Aspects of Rheumatic Diseases.

Monday, 16th

Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. Brodie Hughes: Interpretation of Visual Defects.

Tuesday, 17th

Royal College of Surgeons
5 P.M. Mr. Geoffrey Knight: Neurosurgery in relation to Oph mology.
Royal Society of Medicine, 1, Wimpole Street, W.1
2.30 P.M. *Pathology*. (Wellcome Physiological Research Labora tories, Beckenham, Kent.) Demonstrations on Imm and Experimental Chemotherapy.
5 P.M. Dr. G. Brownlee: film on Chemotherapy of Experim Tuberculosis.
London School of Dermatology, 5, Lisle Street, W.C.2
5 P.M. Dr. W. N. Goldsmith: Pigmentation of the Skin.

Wednesday, 18th

Royal College of Surgeons
5 P.M. Mr. Geoffrey Knight: Neurosurgery in relation to Oph mology.
Royal Society of Medicine
4.30 P.M. *Physical Medicine and British Association of Ph Medicine.* Dr. P. Bauwens: Complex Behaviour of frequency Currents in Simple Circuits.

Thursday, 19th

Royal College of Surgeons
5 P.M. Mr. F. G. St. Clair Strange: Plastic Procedures in Preparation of Amputation Stumps for Limb-fi (Hunterian lecture.)
Royal Society of Tropical Medicine, 26, Portland Place, W.1
8 P.M. Brigadier Sydney Smith: Prisoner-of-war Camps in Middle East.
Chadwick Lecture
4 P.M. (Chelsea Physic Garden, Swan Walk, S.W.3.) Prof. W. Pearsall, D.SC., F.R.S.: Water-supply and Fresh Biology.

Friday, 20th

Royal College of Surgeons
3 P.M. Dr. W. Russell Brain: Exophthalmos apart from End Disease.
4.30 P.M. Dr. Brain: Exophthalmos of Endocrine Origin.
Royal Society of Medicine
8 P.M. *Obstetrics and Gynæcology.* Dr. Engel, Mr. S. Kon, D.SC., Mr. S. J. Folley, D.SC.: Physiology of Breast.

Saturday, 21st

Royal Society of Medicine
2.30 P.M. *Orthopædics.* (Lord Mayor Treloar Hospital, Al Hants.) Sir Thomas Fairbank: Contributions of the Sir Henry Gauvain to Orthopædic Surgery. Prof. T. Po Kilner: Orthopædic and Plastic Surgical Team-w Mr. E. S. Evans: Mechanical Treatment of Tuberc of the Spine and Hip in Childhood. Mr. H. H. Langs Results of Brittain's Arthrodesis for Tuberculosis of Hip.

Appointments

Aspin, John, M.D. Camb., D.M.R.D.: deputy clinical T.O., Leeds.
Goligher, J. C., M.B. Edin., F.R.C.S.: asst. surgeon; St. M Hospital, London.
* Hewitt, Selwyn, M.B., B.HY. Durh., D.P.H.: deputy cou M.O.H., Herefordshire.
Liebert, Katharine, M.B. Manc., F.R.C.S., M.R.C.O.G.: gynæcolo Ancoats Hospital, Manchester.
MacDonald, N. M., M.B. Glasg., D.P.H.: M.O.H., Redcar, Saltb and Marske, and asst. school M.O., North Riding educati committee.
Nelson, M. G., M.D. Belf., M.R.C.P.: clinical pathologist, Roy Victoria Hospital, Belfast.
Tooley, P. C., M.D. Lond., D.P.M.: chief psychiatric asst., department of neurology and psychiatry, London Hospital.

* Amended notice

Queen Mary's Hospital for the East End, London:
Asst. obstetric surgeons:
Barns, H. H. Fouracre, M.B. Lond., F.R.C.S., M.R.C.O.G.
Spiers, B. G., M.B. N.Z., F.R.C.S.E., M.R.C.O.G.

LECTURER IN PHYSIOLOGY,
ST. BARTHOLOMEW'S HOSPITAL
MEDICAL COLLEGE

From the Radcliffe Penicillin Unit of the Medical Research Council

The findings described here have been made on 53 air-borne battle casualties with 63 lacerated wounds, mainly involving compound comminuted fractures of the tibia, and on a further 10 superficial wounds caused by pressure sores and plastic operations.

As only 7 of the lacerated wounds could be completely closed by secondary suture or early plastic repair, the remaining 56 provided an opportunity of following their progress clinically and bacteriologically from first removal of dressings in this unit—generally within the first week after wounding—till they were fully healed from 6 weeks to 18 months later and at every subsequent operation for plastic or orthopædic repair. Since all the patients had received prophylactic injections of penicillin for various periods up to 3 weeks after wounding, and continued to receive prophylactic local applications or intramuscular injections throughout their treatment, the gram-positive organisms commonly considered responsible for major sepsis were of minor significance; and clostridia, though more difficult to eradicate, were not a problem for more than 3 weeks in most wounds. In 1164 swabs hæmolytic streptococci were present 50 times, and *Staph. aureus*, though it appeared in 174 (table I), was readily controlled by local applications of penicillin during the first 6 months of the investigation.

The clinical findings attributed here to infection by gram-negative organisms are those which have been found in wounds which harboured no hæmolytic streptococci or clostridia for 9–48 weeks and in which *Staph. aureus* —i.e., coagulase-positive staphylococci—appeared on isolated occasions only or not at all. Non-hæmolytic streptococci, clostridia, and coagulase-negative staphylococci appeared so erratically that it was impossible to associate any particular condition with their presence; so they are excluded from consideration here.

It had been hoped to compare the state and progress of wounds containing gram-negative bacteria with those of wounds in which these organisms were not present; but 51 of the 56 which could not be closed by secondary suture harboured one or more species of gram-negative bacteria from the second week after wounding onwards. It was therefore impossible to assess effects against a comparable number of controls. The 5 exceptions undoubtedly made steady progress towards healing and bony union, without the interruptions caused by sinuses or sequestra, and the time at which union was consolidated compared favourably with that in wounds completely closed by secondary suture.

CLINICAL MANIFESTATIONS

Acute Manifestations.—In the first 3 weeks after wounding it was difficult to attribute acute manifestations to these organisms, because other factors also were often present, such as foreign bodies, pieces of loose bone, and small necrotic pieces of soft tissue, even after careful excision. Clostridia were often found; nor had chemotherapy eradicated every *Staph. aureus* at this stage.

One purulent arthritis persisted even after *Staph. aureus*, hæmolytic clostridia, and streptococci had been eliminated; and gram-negative bacteria were the only organisms remaining other than non-hæmolytic clostridia.

In another case extensive cavitation of the head of the tibia, with some involvement of the knee-joint, had a clean, bleeding, and sterile surface when first examined 4 days after wounding. There were then no signs of inflammation and little constitutional disturbance.

At each extensive change of dressing and plaster during the next 8 weeks the patient acquired a new infection with a different species of gram-negative organism. He had a swinging pyrexia for about the same time and developed slimy putrefactive-smelling pus in his wound, with minimal formation of granulation tissue.

Clostridia also were cultured on 4 of the 7 occasions on which wound swabs were taken during this time; hence the gram-negative organisms may not have been solely responsible for his condition.

Long-term Manifestations.—Eighteen wounds have given us an opportunity of studying the effects of these organisms alone for fairly long periods. In 8 no *Staph. aureus* or *Strep. hæmolyticus* appeared at any time, and gram-negative organisms alone were present from within 4–10 days of wounding till healing had taken place from $3^1/_2$ weeks to 12 months later. Of these wounds 6 were compound comminuted fractures of the tibia, in the upper, middle, or lower third, where the wound could not be completely closed by early repair, and 2 were large soft-tissue wounds of back and thigh which were sutured but required a drainage-tube for several days, and in consequence a sinus persisted for $3^1/_2$–4 weeks. In the remaining 10 wounds gram-negative infection persisted alone for periods of 9–24 weeks.

All these wounds had undergone early débridement and, in contradistinction to those containing clostridia, had contractile bleeding muscles, no redness of skin edges, and a minimum of slough. After the first definitive operation all these wounds suppurated a little, the pus being mucopurulent and stained lightly with old blood. Growth of granulations was minimal, and there was no breakdown of suture lines or delay in ingrowth of epithelium. There was little constitutional disturbance, pyrexia not being more than 100°F at any time and subsiding below 99°F in 3 weeks in all but one patient, who later developed jaundice. There was no sign of the chronic anæmia associated with sepsis, for the number of red cells rose steadily from 3,500,000 to nearly 5,000,000 per c.mm., and hæmoglobin from about 70% to about 90–100% in the 6 weeks after wounding. Moreover the men's health remained excellent throughout their long convalescence.

The 2 flesh wounds made uninterrupted progress towards healing, and 2 of the compound fractures healed within 7 weeks without any subsequent formation of a sequestrum. Bony union in these was achieved in a time comparable with that in similar fractures whose wounds could be completely closed by secondary suture and so protected from infection at an early stage.

Thus, in the early stages the consequences of this type of infection did not appear to be severe, but its persistence had some serious consequences, for the 4 remaining compound fractures do not present so uncomplicated a picture. Sinuses persisted for various times. In the 2 less severe, 4 months elapsed before the sinus healed, and both later broke down again before final healing took place, 40 weeks after wounding. Sequestrectomy was necessary on several occasions in one, and cultures from the sequestra invariably yielded *Proteus*. In the remaining 2, where bony destruction was greater, sinuses remained not completely healed 9 months and a year, in spite of sequestrectomies and curettings. The bony cavities, which in other cases filled in as the tibia thickened at the site of fracture, remained, and the blood-clot which filled them at each

TABLE I—BACTERIAL FLORA IN DEEP AND SUPERFICIAL WOUNDS THROUGHOUT PROGRESS TO HEALING

† N.H.S., non-hæmolytic streptococci.

operation disintegrated and escaped as thin brown purulent discharge, some poorly developed granulations and a little slimy pus appearing in its place. More than 6 months after the fractures there was no development of firm fibrous tissue and no callus formation.

The remaining 10 wounds presented a similar clinical picture as regards the persistence of sinuses. After clostridia had been eliminated, the thick purulent discharge became thin, sometimes with a putrefactive odour, and eventually brown and slimy, making it easily distinguishable from the thick creamy pus seen in infections with *Staph. aureus* and *Strep. hæmolyticus*. The distinction was so clear that, on several occasions, on the appearance of the latter type of pus a diagnosis of secondary invasion by gram-positive organisms was correctly made before the bacteriological report was available. As the infection with gram-negative organisms came under control and cultures were eventually sterile, the exudate became serosanguineous or serous, and again the result of the swabs could be fairly prognosticated by its appearance.

TABLE II—BACTERIAL FLORA IN 53 SEQUESTRA

Organism	No. of sequestra

Clostridia	3	..
Staph. albus	3	..
Non-hæmolytic streptococci ..	4	..
Sterile	6	6

There was no indication that discharge produced by gram-negative organisms had any irritant action on the skin, provided it was cleared away daily. In fact, epithelial growth proceeded remarkably rapidly till the wounds were no more than sinuses. If, however, the wounds were enclosed in plaster or in an occlusive dressing for several weeks, the surrounding skin was invariably excoriated. More disconcerting than the persistence of sinuses was the ability of epithelium to grow over their mouths, giving the appearance of a completely quiet fracture site without pain, tenderness, or redness. Evidence that a pathological state still persisted consisted only in the lack of callus formation visible on radiography or in the development of sinuses after the patient's leg had begun to bear weight.

Sequestra were on several occasions removed from these sinuses. When the cavities in which they lay were opened up they presented the same appearance as those already described. Bacteriological examination of the material removed revealed no other organisms than *Bact. coli*, *Proteus*, or *Ps. pyocyanea*. Among the 53 cases, many sequestra were removed from 21 wounds, and 53 were examined bacteriologically. Only 3 were infected with *Staph. aureus*, 6 were sterile, and cultures of the remaining 44 yielded *Bact. coli*[1] in 29 instances, *Proteus* in 20, and *Ps. pyocyanea* in 18 (table II).

The blood-clot which filled the bony cavitie af sequestrectomies, if sterile, remained intact and form a basis for the ingrowth of organising tissues and an epithelial covering; but, if infected with gra negative organisms, it steadily disintegrated, leaving foundation for repair. (Though *Bact. coli* does not, b *Proteus* and *Ps. pyocyanea*, liquefy proteins in vitro, appears to have interfered at some stage in the proc of organisation, as shown by the number of seque infected by it alone.) Such infection of the clot appea to be the reason for lack of union and the developm of sequestra, and it would have been legitimate ascribe to it the failure of bone grafts, had these be undertaken while the organisms were well establish When it was possible to close the wound early or prevent infection with gram-negative organisms, so limbs which were seen on radiography to have ma small fragments of bone and shell distributed among muscles or between the ends of bone did not devel sinuses. In other words, the fragments which mig have become sequestra were incorporated in the call

The 10 surface lesions gave no evidence that gra negative bacteria had any clinical significance. The organisms were much more tardy in making their fi appearance and were often overshadowed by the presen of *Staph. aureus* (table I). There were no blood-clots a seldom any dead tissue in these wounds, which theref offered a very different type of pabulum for organisms

COMBATING INFECTION WITH GRAM-NEGATIVE ORGANIS

It therefore seemed advisable that every effort shou be made to combat gram-negative organisms and compare the effects of the different agents already our disposal in eliminating them. Even if those tri were not very effective, the serial examination mig at least provide a standard against which to judge t effects of new and more powerful agents as they appea The effects of local application of different drugs we therefore observed besides those of other agenci expected to influence wound infection.

Agents used were as follows:

(1) Streptomycin[2]:
  (*a*) a powder containing 235 units per mg.;
  (*b*) mixed with sulphamezathine, 10,000 units per (1 wound);
  (*c*) an aqueous solution, 12,500 units per c.cm.;
  (*d*) a cream, 12,500 units per g.
(2) Kojic acid[3]:
  (*a*) the crystalline substance mixed with an equ part of magnesium carbonate to form a powder for insufflation;
  (*b*) neutralised aqueous solution, 1 : 200.
(3) Sulphathiazole;
  (*a*) in microcrystalline form as an insufflation, wi penicillin, 2000–5000 units per g.,
  (*b*) an aqueous solution of the sodium salt ('Cib zol') 1 g. per 5·5 c.cm. for irrigation of sinuse
(4) Sulphamezathine:
  (*a*) and (*b*) as described for sulphathiazole, th solution containing 1 g. per 3 c.cm.

---

[1] At least one found to be hæmolytic.

[2] Concentrations used were worked out on a basis of 50 uni being equivalent to 1 unit of penicillin.

[3] Kojic acid is an antibiotic which is stated to inhibit *Bact. co* and *Proteus* at 1 in 400, and *Ps. pyocyanea* at 1 in 16,000 1 in 32,000, and to be non toxic to human leucocytes in vit at 1 in 400 (Jennings and Williams 1945).

(5) Proflavine :
 (*a*) a powder—proflavine hemisulphate 1% in sulphathiazole—'Thiazamide' (1 wound only);
 (*b*) an aqueous solution—'Isoflav' 1 : 1000 buffered to a pH of 6·3.
(6) 'Phenoxetol' : an aqueous solution, 1 : 45.
(7) Ammophenol : an aqueous solution, 1 : 1000.
(8) Eusol or 'Milton' : an aqueous solution, half strength.
(9) Penicillin :
 (*a*) a powder containing at least 100,000 units per g. ;
 (*b*) an aqueous solution, 500 units per c.cm. ;
 (*c*) a cream, 250 units per g.

Five was considered the least number of wounds om which any conclusions could be drawn about the ficacy of any agent ; but, inasmuch as the sulphonmides were used as a diluent for penicillin powder in he routine prophylactic insufflation, after dressings, gainst infection with gram-positive organisms, they had any more unintentional trials than the other agents.

Besides the changes of flora following the daily use f chemical agents, those following enclosure in plasterf-paris alone were recorded. Operation, when it nvolved excision, removal of sequestra, and curetting, ras also regarded as a possible cause of elimination of nfection. Finally, the presence of other organisms in he wound was thought to be a possible factor in the ontrol of infection with gram-negative organisms. There was no doubt that such infection flourished rrespective of the presence of non-hæmolytic streptoocci and of clostridia. Hæmolytic streptococci appeared o infrequently as to make it useless to draw any deductions from their presence, but *Staph. aureus* persisted everal months in 2 wounds and long enough in others to make it worth while to record its association with the gram-negative organisms.

As a control against which to measure the effect of the other agents, the results of swabs taken during penicillin applications without sulphonamides are recorded, for the three gram-negative bacteria in question all flourished on this treatment.

BACTERIOLOGICAL INVESTIGATIONS

All the 73 wounds were examined by serial swabbings taken from the time when the first dressings were removed till the wounds were healed. Windows were cut in plasters for this purpose and later to allow the daily dressing and application of local agents. Examinations were made weekly or twice a week during periods of observation, the only exceptions being those cases in which the effect of complete enclosure in plaster was being tested.

First Appearance.—*Bact. coli* was the earliest invader. In 50% of all wounds examined in their first week this organism had already appeared. *Proteus* appeared most often in the second week, and *Ps. pyocyanea* in the third. Fresh infection still continued after this ; hence by the end of 6 weeks, and in spite of a no-touch technique during ward dressings, all but 1 of those still unhealed had been infected with *Bact. coli*, and all but 6 with *Ps. pyocyanea*. *Proteus*, which at this time had not yet been found in 14, first appeared in a further 8 wounds during the following 21 weeks. *Bact. coli* and *Ps. pyocyanea* first appeared after operation as often as after ward dressings in spite of the many more opportunities the dressings provided. *Proteus* first appeared more often in the ward. Table III shows the order of appearance of these organisms, and table I indicates their persistence in spite of measures taken to eradicate them.

* Remainder healed.

Methods of Recording Results of Treatment.—The results of the bacteriological examinations were charted concurrently with the type of local treatment applied and during a period of follow-up after treatment had been discontinued. These records were then compared with the incidence of any particular type of infection before treatment began. Since operations and replastering were necessarily performed irrespective of courses of local treatment, it was impossible to give every agent the same length of trial and the same period of follow-up after the cessation of treatment. Results are not recorded unless daily applications were used for 5 days or more—most trials lasted between 10 days and a

fortnight. The variation in length of treatment, and consequently in the number of swabs taken, might have led to erroneous comparisons; for this reason the number of wounds examined in each week, besides the percentage of swabs from which organisms had disappeared, have been recorded for the assessment of results.

A follow-up of a fortnight was attempted; but, if cultures became positive again after the disappearance of the test organisms, the possibility of the introduction of extraneous infection had to be considered, and so the time for follow-up was limited by procedures which enhanced this risk. Records also had to be excluded where another agent had to be used, or *Staph. aureus* appeared during what should have been the follow-up period. The number of wounds examined during the follow-up period is thus less than those examined during treatment.

As swabbings could not be done on wounds enclosed in plaster, those taken immediately after its removal are recorded in the treatment columns, the follow-up being regarded as a more useful criterion, for the first swab alone might have given an erroneous impression owing to the presence of bacteria in the accumulated secretion. The same procedure was adopted for recording the effect of operations.

A further difficulty in interpretation arose from the fact that, while the wounds were large and comparatively fresh, serial sampling did not consistently yield the same gram-negative flora, in spite of the care taken to swab all parts of the wound. For instance, if *Bact. coli* disappeared after 3 consecutive positive swabbings, this was no criterion of its complete disappearance from the wound. A ratio of the order of 1 negative to 5 positive cultures was usual, even in the absence of specific treatment. On the other hand, when wounds were reduced to chronic sinuses, one type of flora was much more persistent, and one culture free of them had correspondingly greater significance and was often followed by healing. From these considerations it was realised that a series of swabs was needed before one could conclude that any particular organism persisted in a wound, or that any particular agent had had an effect.

It was clearly useless to regard the single swab immediately preceding treatment as the criterion of the presence or absence of a specific infection. Instead, a standard for each wound was made, based on all the swabbings from the time a particular organism first appeared. The effect of an agent was assessed by comparing the percentage of swabs from which the bacteria were absent after treatment had begun with the percentage during the preceding time. Tables IV, V, and VI show these percentages before and after beginning treatment with the various agents. In an ideal result the percentage would be well below 50 for the whole time before treatment began, rising steadily during each week of treatment, and maintaining a high figure after treatment had ceased, thus indicating that the agent had not only disinfected the wound secretions while present but also eliminated organisms from the surrounding tissues. The best order of precedence for the agents would be based on the degree in which they reduced the bacterial population during the follow-up. As, however, all wounds could not be observed in this period, and all agents were not applied for the same length of time, it was thought fairer to use an earlier criterion also. For practical purposes any treatment should produce an effect within a fortnight, and so the improvement obtained at this time is also recorded. These criteria of improvement are placed in the last two columns of the tables and are computed from the difference between the original percentage preceding treatment and that found at these times.[4] The improvement in the follow-up provides a check on the earlier figure and occasionally demonstrates the inability for improvement to be maintained after treatment was discontinued—e.g., kojic acid's action against *Bact. coli*.

Results.—A comparison of the results in each table shows that whereas some agents have some effect on *Bact. coli*, streptomycin is the only one for which the differences remain high for all three organisms. (Though only 2 wounds infected with *Proteus* were treated, they both had long-standing and persistent infections.) Sulphathiazole ranks next to it in its ability to eliminate *Bact. coli* and *Proteus*, and sulphamezathine in its almost equally good effect on *Bact. coli* and *Ps. pyocyanea*. Proflavine had the best effect on *Bact. coli* during application, but it did not maintain so great an improvement once treatment was discontinued. Eusol and milton were used on superficial wounds only, but their effect on *Ps. pyocyanea* on these easily accessible lesions was very good. The presence of *Staph. aureus* produced results of the same order as did the two sulphonamides.

---

[4] For easier comparison table VII isolates the positive findings from those where there was no improvement.

The remaining agents did not produce consistent enough results for them to be classed in the same category as those already discussed. Aminophenol, though it appeared to have a very good effect on *Bact. coli*, cannot be assessed on the results obtained from 2 wounds only. Pursuit of further trials was not encouraged by finding that, on incubation with *Bact. coli* in slide cells and in the presence of whole blood, it did not inhibit the organism when diluted more than 1 : 4000, whereas proflavine inhibited up to 1 : 32,000 when similarly tested. With *Ps. pyocyanea* neither proflavine nor aminophenol produced inhibition at a dilution of 1 : 4000.

CLINICAL APPLICATION OF FINDINGS

The differential action of most agents, whereby they inhibited one species of bacterium more than another, was not appreciated till more than 6 months had elapsed from the beginning of the trials; hence, before the knowledge described here was obtained, no rational simultaneous or consecutive treatment of wounds with these agents was adopted. When one organism had disappeared under one treatment, another often remained to confuse the issue; hence treatment was abandoned without its being realised that some good had been done. By the time the results of the investigation became clear, not many persistent sinuses remained to be treated. Three which were infected with *Proteus*, having persisted unhealed 6 and 8 months, were rendered sterile and healed in 1–3 weeks following daily irrigations with sodium sulphathiazole (cibazol 1 g. per 5·5 c.cm.) for a fortnight. A fourth was cleared of *Staph. aureus* and *Ps. pyocyanea* by irrigations with penicillin and sulphamezathine, drying and healing within a week of cessation of treatment. The 6 sinuses which were treated with streptomycin were all more than 8 months old. With one exception they became sterile during treatment and made steady progress towards healing, which was complete within 3 weeks of the end of treatment. The exception contained *Staph. aureus* and *Strep. hæmolyticus*, and these did not disappear, nor did the lesion show progress towards healing, till penicillin paste was substituted for the streptomycin. After eventual subsidence of infection, as a prophylactic measure at operation for bone grafting, a combination of sulphathiazole, sulphamezathine, and 100,000 units of penicillin (for dose see Florey et al. 1946) in a powder form was sprinkled into the wounds. Inlay and chip grafts were subsequently laid in these, care being taken to secure hæmostasis with adrenaline 1 : 1000 before inserting the powder. These cases have all progressed uninterruptedly to consolidation without persistence of sinuses or the necessity for removing their vitallium screws. Such uniformly successful results cannot be claimed for 3 other grafts where local prophylactic chemotherapy was not used.

Staph. aureus ..	23	25	24	24	19	28

It should be emphasised that this reduction of infection has only been obtained by cleansing of the wound in addition to the daily applications, and by constant attention to the guiding principle that, to produce the desired effect, full access to the infected part must be obtained. For this reason forced irrigations were used for sinuses, insufflations being reserved for surface infections and for the treatment of wounds at operation, after hæmostasis had been secured and when a good access could be obtained to all possibly infected parts.

Only 2 minute and occasional sinuses now remain of the 63 originally severe wounds 20 months after they were first inflicted, and there has not been any sign of breakdown since healing took place in the remainder 4 to 18 months ago.

DISCUSSION

The effectiveness of penicillin in eliminating gram-positive organisms has brought to the fore the problem

* Usually with penicillin.

10 superficial wounds. Lysis of surrounding clot, persistence of discharge, and consequent interference with the processes of bony and soft tissue repair seem to be their main effect.

No unequivocal evidence was obtained that when one they produced toxæmic effects.

Bacteriological and clinical effects were observed of e daily local application of different agents in reducing e infection.

Streptomycin was the most effective in removing act. coli, Ps. pyocyanea, and Proteus both rapidly and ermanently in a few wounds.

Sulphathiazole was effective in eliminating *Bact. coli* nd *Proteus* to a lesser degree.

Sulphamezathine had a similar effect on *Bact. coli* and *s. pyocyanea.*

Eusol and milton appeared to have a good effect on *s. pyocyanea.*

The presence of *Staph. aureus* in the wound was almost s effective as the two sulphonamides in reducing the ram-negative population; nor was there any evience that daily applications of penicillin increased heir number when they were the only organisms resent.

Neither operation nor enclosure in plaster-of-paris ad any pronounced influence on the infection.

Clinical application of these findings showed that eliberate use of the sulphonamides, with penicillin hen necessary, or the use of streptomycin, could terilise persistent sinuses so that they healed rapidly.

We wish to thank the Sir William Dunn School of Pathology nd Prof. A. D. Gardner for providing us with facilities for oing the bacteriological work; Dr. R. L. Vollum and his taff, who carried on these examinations after one of us R. W. N. L. R.) had left the unit; Dr. Audrey Smith, for the arliest bacteriological investigations; Colonel J. S. Jeffrey, or allowing the work to be carried out on what were originally is cases; Messrs. H. Truelove and R. H. Snow, for their ssistance in keeping records; the nurses, for their patience during the prolongation of dressings that so many observations ecessitated; Dr. E. S. Duthie and Sir Hugh Cairns, for paring us a portion of their exiguous supplies of streptomycin; nd Dr. Mary Barber, Dr. J. Gough, Dr. M. A. Jennings, nd Mr. T. L. Williams for supplies of aminophenol, phenoxetol, nd kojic acid.

DIETETIC DEFICIENCY SYNDROMES IN INDIAN SOLDIERS

J. H. WALTERS
M.B. Camb., M.R.C.P.
LIEUT.-COLONEL I.M.S.

MANY members of an Indian infantry battalion developed, while on active service, a syndrome characterised by severe wasting, chronic steatorrhœa, and macrocytic anæmia, accompanied by evidence of specific deficiencies of the vitamin-B complex. Three-quarters of this battalion were Jats and a quarter Rajputana Mussulmans, the former habitual vegetarians, the latter meat-eaters. The Mussulmans, recruited from unfertile areas of Rajputana, tend to be smaller and more lightly built than the Jats.

The unit was ordered from Madras to Calcutta in November, 1943, to take part in famine relief measures. It remained in the Calcutta area until April, 1944. During this period the men were exposed to no hardships but were fed on the active-service scale of rations, in which the only source of animal protein acceptable to the vegetarians was condensed milk, of which each man received 2 oz. daily with which to make his tea. The Mussulmans ate a 6-oz. meat ration twice or three times a week, but in other respects their diet was at all times identical with that of the Jats.

The men were engaged on guard, loading, and food-escort duties, and any groups sent on convoy duty, when feeding difficulty might have arisen, were changed in rotation.

The battalion left Calcutta to share in the relief of Kohima and was stationed on the recaptured Treasury Hill from May 17 to May 27, 1944. After this it occupied a Naga village on the farther side of the valley and remained there until August 23, 1944. Both these areas had been the scene of much bitter fighting, and there were swarms of flies attracted by the dead. Consequently most of the men developed diarrhœa or frank dysentery, and those who escaped had little relish for their food.

From Burma the battalion was withdrawn to India, reaching its camp on Sept. 1, 1944. Next day many men reported sick; and, of a strength of 815, 126 were admitted to hospital with nutritional defects, while 349 others were excused all duties and given a special supplemented diet.

This paper describes the 42 worst cases, which were transferred to an Indian base general hospital for further investigation and treatment. Of these patients 3 were Mussulmans and the other 39 Jats (all previously vegetarians). Each patient said his illness had begun about two months before the withdrawal of the battalion from the fighting area. The initial symptom was loss of appetite, followed by increasing distension after food, and diarrhœa, with large pale pultaceous frothy stools. The tongue then became sore, and wasting and extreme weakness rapidly developed. These symptoms seemed to have been precipitated by diarrhœa in 6 cases, clinical bacillary dysentery in 16 cases, amœbic dysentery in 5 cases, and malaria in 10 cases.

The following broad clinical syndromes were encountered: (1) gross alimentary dysfunction, with steatorrhœa; (2) macrocytic anæmia; and (3) alimentary dysfunction combined with macrocytic anæmia.

ALIMENTARY DYSFUNCTION

Changes in Tongue and Mouth

Two distinct changes were noted in the epithelium of the tongue:

(1) A smooth glazed mauve surface beneath which no papillæ could be recognised. These atrophic changes were either generalised or localised to strips on either side of the median fissure, and caused soreness and burning. The tongue was small and pointed.

(2) A bright magenta inflamed surface without atrophy, rarely generalised, usually confined to the margins and tip. In the affected areas each fungiform papilla appeared swollen, with its summit eroded and conspicuous as a red dot. These changes were associated with aphthous ulcers on the tongue

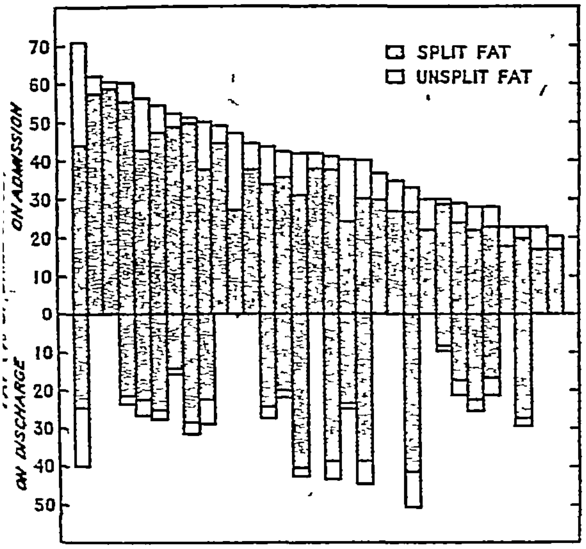

Fig. 1—Analyses of fæcal fat.

of the vitamin-B_2 complex. Since it was impossible to persuade habitual vegetarians to take a flesh diet, a high-calorie diet, with milk as the main source of animal protein, was prescribed for them, no attempt being made to limit fats and carbohydrates (table I).

Liver soup prepared from 8 oz. of fresh sheep's liver was given to each man daily: at first some difficulty was experienced in persuading the vegetarians to take this, but all soon agreed to do so.

Vitamins and Drugs

Intensive vitamin therapy was used in most cases.

Crude vitamin-B group was supplied in the form of a liquid culture of baker's yeast; an empirical dose of 3 oz. daily was given.

Nicotinic-acid tablets were used in 28 cases, the oral dosage being as follows:

300 mg. daily	9 cases
" " " rising to 500 mg. daily	16 "
" " " " " 600 " "	1 case
" " " " " 750 " "	1 "
" " " " " 1000 " "	1 "

Parenteral nicotinic acid 100–200 mg. daily was given over short periods to 6 patients, in whom an absence of sensations of flushing and burning following ingestion of the tablets suggested that the alimentary canal was not absorbing it.

Riboflavine was given in short courses of 9 mg. daily for four days to 16 patients, 11 of whom required repeated courses, up to six in number.

Liver extract (Teddington Chemical Factory, Bombay), 4 c.cm. every second or fourth day, was given parenterally to cases of severe macrocytic anæmia and proved effective.

Sulphaguanidine in standard doses was given to 16 patients who developed diarrhœa with cellular exudate; 9 required repeated courses up to three in number. Iron, as ferrous sulphate, was given in doses of gr. 32 daily whenever hypochromia was encountered.

Blood-transfusion

Since it has been my experience that cases of nutritional macrocytic anæmia whose initial red-cell counts are below 2,000,000 prove unresponsive even to massive parenteral liver therapy until blood-transfusion also has been given, transfusions were given as a routine to all such patients. Stored blood 36–48 hours old was obtained from a base transfusion unit. The following blood-transfusions were given:

Blood-transfusion total 2 pints given to	6 patients
" " " 4 " " "	1 patient
" " " 6 " " "	1 "
" " " 7 " " "	1 "
" " " 10 " " "	1 "

The last patient, who was very anæmic and had severe watery diarrhœa on admission, bled heavily from internal piles and became dangerously exsanguinated before this source of blood-loss was stopped by local injections of sclerosing fluid.

Plasma transfusions were given to 5 patients with peripheral œdema and hypotonia, suggesting hypoproteinæmia. 'Lyovac' dried plasma, reconstituted to double strength, was used; 4 bottles, equivalent to the plasma from 1000 c.cm. of blood, was the usual dose. Two patients received 1 such transfusion, two others received 2, and one received 3.

RESULTS

Two patients died. Their histories were as follows:

Case 3.—A Jat vegetarian, aged 22, showed on admission extreme cachexia, considerable hypotonia, and macrocytic anæmia (red cells 2,160,000 per c.mm., Hb 7 g. per 100 c.cm., colour-index 1·13). The plasma-protein level was low, total 4·25 g. per 100 c.cm. (albumin 2·48 g., globulin 1·65 g. per 100 c.cm.), and there was much steatorrhœa (total fat 47·8%: split 56%, unsplit 44%). He received transfusions of 500 c.cm. of twice-concentrated plasma on two occasions, but two days after the second transfusion he developed a heavy subtertian malarial relapse and died of peripheral circulatory failure.

Case 4.—A vegetarian Jat, aged 25, was received in an emaciated condition (red cells 1,680,000 per c.mm., Hb 7 g. per 100 c.cm., colour-index 1·54, mean corpuscular volume 139 c.μ, mean corpuscular hæmoglobin 45·6 μμg. The stools were loose but showed only slight excess of fat. (Total fæcal fat 28%; split 79%, unsplit 21%.) He was transfused with 2 pints of whole blood and showed improvement on oral nicotinic acid. He then had a subtertian malarial relapse, with acute diarrhœa. He was again transfused with 2 pints of blood with benefit. Shortly after this he developed clinical dysentery, causing circulatory collapse, for which a transfusion of $1^1/_4$ pints of twice-concentrated plasma was given by slow drip over six hours. This caused great improvement in the pulse-rate and blood-pressure, which was unfortunately only transient, for he developed acute *pulmonary œdema* two

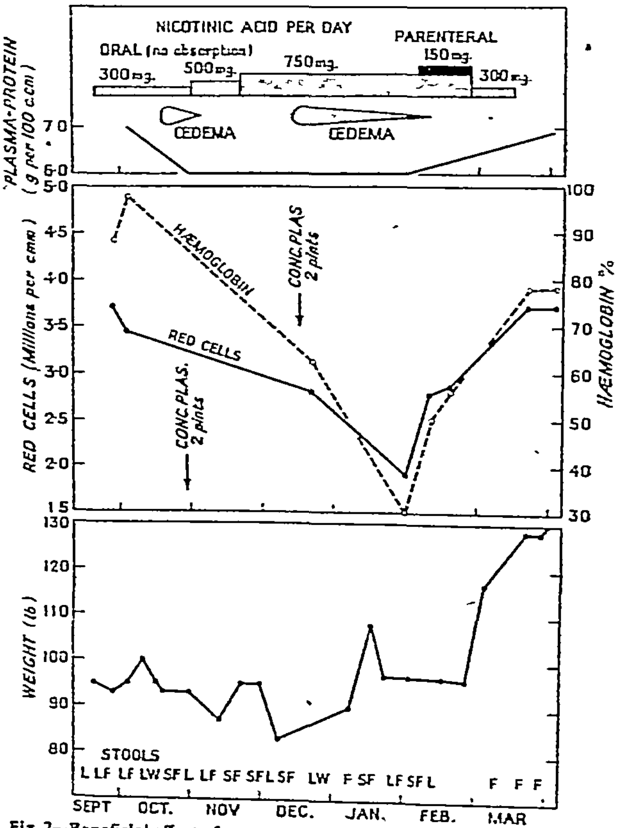

Fig. 2—Beneficial effect of parenteral nicotinic acid. Hb 100% = 14 g. per 100 c.cm. Stools: L, loose; LF, loose and fatty; LW, loose and watery; SF, semi-formed; F, formed.

hours after the completion of the transfusion and quickly died.

Necropsy showed old bacillary ulceration of the colon, and pulmonary œdema due to left-sided cardiac failure.

Three patients were invalided out of the Army. Two of these had developed intercurrent pleurisy with effusion, but both were in a state of excellent nutrition before their discharge from hospital; the third patient, when in a very good general condition, had to be invalided because of a progressive osteoarthritis of the hip due to trauma. The remaining 37 patients were retained in hospital until their general nutrition was good, their alimentary function appeared normal, and their blood picture was either normal or rapidly recovering. Of these 37 patients, 11 on discharge had red-cell counts of between 3,200,000 and 4,000,000 per c.cm., with slight macrocytosis (mean corpuscular volume up to 105 c.μ). Parenteral liver therapy had only been given to 2 of these.

TABLE II—ATTA AND RICE IN ACTIVE-SERVICE DIETS OF INDIAN TROOPS

Type of diet	Calories	Protein (g.)	Carbohydrates (g.)	Fat (g.)	Riboflavine (mg.)	Nicotinic acid (mg.)
Non-vegetarian:						
Atta 20 oz.	3832	118·2	548 8	129·2	1·52	43·4
Atta 10 oz., rice 10 oz.	3832	104·0	508·0	134·0	1·33	34·4
Vegetarian:						
Atta 20 oz.	3508	93·0	508·0	110·6	1·22	32·4
Atta 10 oz., rice 10 oz.	3568	79·0	568·0	110·0	1·03	23·0

In addition, 9 cases showed some residual steatorrhœa, with total fæcal fats up to 37%, but were passing only one formed stool of normal bulk daily, were well covered and free from tympanites, and had good appetites.

The results may be summarised as follows:

Recovered on diet and liquid yeast alone ..	13 out of 37 = 35 %
Recovered on diet and yeast and oral nicotinic acid	9 out of 37 = 24·4 %
Recovered on diet and yeast and oral nicotinic acid and parenteral liver therapy	9 out of 37 = 24·4 %
Recovered on diet and oral and parenteral nicotinic acid and parenteral liver therapy	6 out of 37 = 16·2 %
	37
Died	2
Invalided	3
Total	42

DISCUSSION

The cases described represent the results of a parallel experiment in two groups of men—one vegetarian, the other taking the same diet with the addition of a meat ration—who had been exposed to the same privations and suffered equally from enteritis, dysentery, and malaria. There were 13 times as many cases of grave malnutrition and anæmia among the vegetarian Jats as among the meat-eating Rajputana Mussulmans, though a quarter of the battalion were Mussulmans.

Malaria, to judge by the relapse-rate, since it occurred in only 25% of the cases, was an unimportant ætiological factor. On leaving the forward area the unit ceased to take "suppressive mepacrine."

Bowel infections seem to have been an important precipitating factor, having developed in 67% of patients, most of whom dated their presenting symptoms from such an attack. However, had such bowel infections been the main cause, a disproportionately high incidence among the vegetarians should not have been found.

That at the height of the illness a general absorptive defect was present is suggested by the fact that in 6 severe cases no symptoms of vasodilatation followed the ingestion of very large doses of nicotinic acid, ranging from 500 mg. daily in 4 cases to 700 mg. daily in 1 case, and even to 1000 mg. daily in 1 case. With the general and digestive improvement consequent on parent nicotinic-acid therapy (150 mg. daily for 10–14 day all these cases regained the power to absorb oral nicoti acid and complained of flushing and burning of the s when given only half the original dose.

The beneficial effect of parenteral nicotinic-acid therapy is shown in fig. 2.

The occurrence of clinical hyporiboflavinosis, which might relapse, during the recovery phase is of interest, since it conforms with reports of the sudden appearance of specific hypovitaminotic syndromes in civilian internees in Germany recovering from long-continued starvation.

The syndrome shown by most of these cases was that of sprue and seemed similar to that observed among British personnel from Burma, except that the incidence of grave macrocytic anæmia was higher in this series than in reported series drawn from British troops.

The disproportionately high incidence among the vegetarian group conforms with the report of Taylor and Chhutani (1945), who noted an incidence of anæmia, mainly macrocytic, 22 times greater in vegetarian than in meat-eating troops in Iraq. Table II sets out the important constituents of various Indian diets, according to the active-service scale.

These diets are adequate in all essentials provided they are taken in full, but they are bulky and tim consuming both to prepare and to eat. There is som evidence (Major H. Lehmann, R.A.M.C., personal communication) that, under peace conditions, the Indian soldier taking two meals a day may eat no more than 60% of his total atta (whole-meal flour) ration, and probably this also obtains under campaign conditions. If so, the vegetarians' intake of nicotinic acid and riboflavine, which depends chiefly on his atta consumption, can easily fall below the safe levels of 15 mg. and 1·4 mg. daily. An alimentary infection, by reducing intake and interfering with absorption, may precipitate a state of deficiency in men who for several months have been taking barely adequate amounts of these two essential vitamins.

Deficiencies of riboflavine and of nicotinic acid lead to distinct changes in the epithelium of the tongue. Whereas nicotinic-acid lack is characterised by atrophy of the papillæ, associated with gross failure of absorption from the alimentary tract, riboflavine deficiency causes swelling of individual papillæ (especially the fungiform), with erosion of their apices. This appearance is often associated with well-recognised lip lesions, but riboflavine deficiency by itself does not appear to cause any other disturbance of alimentary function.

The changes described here resemble those reported by Everley Jones et al. (1944), who suggest that even extreme atrophy may respond to riboflavine therapy. Such a response was not found in the present series, among whom such cases improved and showed regeneration of the papillæ only when large amounts of nicotinic acid were given, usually by injection.

SUMMARY

Deficiency syndromes among Indian troops on active service are described. The high incidence of these syndromes among vegetarians, as opposed to meat-eaters suggests that the deficient factors are derived from animal protein; but intestinal infections play an important precipitating rôle.

A syndrome superficially resembling sprue commonly results. This responds specifically to nicotinic-acid therapy, though parenteral administration may be necessary.

Distinction is made between the tongue changes associated with deficiencies of riboflavine and of nicotinic acid.

I wish to thank Major-General T. O. Thompson, D.M.S. in India, for permission to publish this hurjaty, I.A.M.C., for much clinical assistance; Major Monte, I.M.S., I.A.M.C., and Dr. V. Korke for laboratory vestigations; and Brigadier H. K. Goadby for his advice d criticism in tho preparation of this article.

ATYPICAL PNEUMONIA

SIGNIFICANCE OF COLD AGGLUTININS

G. E. O. Williams
M.D. Lpool, M.R.C.P.
ASSISTANT PHYSICIAN, BIRMINGHAM UNITED HOSPITAL;
LATE SQUADRON-LEADER R.A.F.V.R.

The condition at present known as "atypical pneumonia" or "virus pneumonia" may be a group of diseases similar in clinical manifestations but of different ætiology. This view has been stated by Drew et al. (1943) and supported by many others. There is little doubt that most, if not all, of these cases are of virus origin (Longcope 1942, Weir and Horsfall 1940, Eaton et al. 1941, 1944, Francis and Magill 1938, Commission on Acute Respiratory Diseases 1945).

In an attempt to discover some variations in the clinical picture which might be attributable to differences in ætiology, the records of 56 patients admitted to a R.A.F. hospital in twenty-one months were examined. Clinical, pathological, and radiological findings were reviewed, and particular attention was paid to the tests for cold agglutinins which had been performed in most instances.

The standards by which atypical pneumonia was diagnosed have been described elsewhere (Drew et al. 1943, Longcope 1940, 1942, Kneeland and Smetana 1940, Ramsay and Scadding 1939). The present series corresponded closely to those of other workers in the incidence and duration of individual signs and symptoms, in values obtained for sedimentation-rates and leucocyte counts, and in radiological findings.

COLD AGGLUTININS

The primary object of this investigation was to assess the significance, if any, of the cold-agglutinin titre in these cases. Out of 51 cases in which this test was performed, 26 had titres of 1 : 64 or higher. The incidence of cold agglutinins at various stages of the disease is shown in table I. Maximal titres developed during the second and third weeks. This is consistent with the findings of other workers (Commission on Acute Respiratory Diseases 1945, Turner et al. 1943, Humphrey 1945).

To enable the cold-agglutinin titres to be correlated with other features of the disease the series was arbitrarily divided into "*cold-agglutinin positives*," comprising the 26 with titres of 1 : 64 or more, and "cold-agglutinin negatives," which had titres below this figure. To exclude errors arising from tests taken at irrelevant periods in the course of the illness, only cases in which cold agglutinins were tested during the second, third, or fourth week were included. The series was next divided into groups according to differences in certain individual features, and the incidence of positives similarly calculated in each group. The significance of the differences between the incidence of cold agglutinins in these subgroups was then assessed by the usual statistical method.

TABLE I—INCIDENCE OF COLD-AGGLUTININ TITRES AT VARIOUS STAGES OF ATYPICAL PNEUMONIA

Titres	Week of illness					
	First	Second	Third	Fourth	Fifth	Sixth and later
Total cases tested ..	14	23	30	17	13	12
1 : 16 and over	4	16	20	14	8	8
1 : 64 and over	1	9	15	7	5	4
1 : 128 and over	1	6	10	4	3	0

There was no significant correlation between the incidence of cold agglutinins and duration of the disease, duration of pyrexia, duration of radiological abnormalities, or incidence of pleural involvement.

Comparison of the incidence of cold-agglutinin positives with the various types of radiographic appearances, however, produced some interesting findings. The radiograms were not available, but the radiologists' reports showed three main types of radiological abnormalities. These are analysed in table II and related to the incidence of cold-agglutinin positives.

The standard error of the difference between the proportion of positives in groups A (28·6%) and C (75%) being 14·6, this difference appears to be statistically significant.

Another clinical feature in 20 of the present cases of atypical pneumonia was "migration" of the pneumonic process from one lobe to another. Of these migratory cases 18 were detected clinically and 15 presented radiological signs. Since this phenomenon was not especially sought for, some cases of migration may have been missed. The number of cold-agglutinin positives among the migratory cases, however, was 15, compared with 7 in a group of 20 cases not showing migration. The difference between these two proportions being greater than double the standard error (14·4), this also appears to be significant.

TABLE II—ANALYSIS OF RADIOLOGICAL FINDINGS IN ATYPICAL PNEUMONIA IN RELATION TO THE INCIDENCE OF COLD AGGLUTININS

Radiological findings	No. of cases	No. of "cold-agglutinin positives"
(A) Partial or complete consolidation of "lobar" distribution confined to one lobe	14	4
(B) Striation or "increased bronchovascular markings"	6	0
(C) Localised mottling and/or patchy areas of consolidation	28	21
Totals	48	25

The 15 cases of migratory atypical pneumonia which gave cold agglutinins are summarised in table III, with the maximal titre of cold agglutinins and the radiological findings. Of these 15 "migrators," 14 showed mottled lung shadows. The radiological reports of the 15th case suggested that it might also have been included in this category, but the information given was not sufficiently conclusive.

The close association of cold agglutinins, migration, and the mottled type of lung shadows suggests that these cases may have a common origin, and table IV, showing the parallel seasonal incidence of cold-agglutinin positives and migration, lends further support to this possibility.

DISCUSSION

Opinions on the significance of cold agglutinins in atypical pneumonia vary considerably. Peterson et al. (1943) found them to be rare, and Stats and Wassermann (1943) consider the test to be "no more than a laboratory curiosity" apart from a few cases of hæmolytic anæmia and Raynaud's syndrome. Turner (1943) found them in 10 out of 22 cases of atypical pneumonia, Turner et al. (1943) in 28% of 132 cases, and Turner (1945) in only

1 out of 39 tests. Viswanathan and Natarajan (1945), however, found titres of over 1 : 256 in 3 out of 5 cases, the Commission on Acute Respiratory Diseases (1944) found cold agglutinins in 31% of cases, and McNeil (1945) found that the incidence of cold agglutinins differed in different outbreaks.

This wide variation can be explained by one of three possibilities: (1) the test may be entirely irrelevant and the positives due entirely to chance (the difference between their incidence in cases of atypical pneumonia compared with controls, coupled with the demonstrable rise and fall in titre during the course of the illness, render this supposition unlikely); (2) the discrepancies might have been due to errors or differences of technique or to some of the tests having been performed at the wrong stage in the illness; and (3), as McNeil (1945) suggested, cold agglutinins may be present in significant titres in only certain outbreaks of the disease. If the third explanation is correct, the cases with cold agglutinins would be expected to have a common and distinctive ætiology.

TABLE IV—SEASONAL INCIDENCE OF (a) TOTAL CASES, MIGRATING CASES, AND (c) COLD-AGGLUTININ POSITIVE THREE-MONTHLY PERIODS

Type of case	Sept.–Dec., 1943	Jan.–Mar., 1944	Apr.–June, 1944	July–Sept., 1944	Oct.–Dec., 1944	Jan.–Mar., 1945	Apr.–June, 1945
Total cases ..	11	11	5	3	3	8	4
Migrating ..	5	8	3	1	1	2	[illegible]
Cold-agglutinin positive ..	4	9	5	1	1	4	[illegible]

Atypical pneumonia is almost certainly of virus origin; but there are probably several viruses capable of producing this clinical picture (Drew et al. 1943, Weir and Horsfall 1940, Francis and Magill 1938, Eaton et al. 1941). It is suggested that patchy radiological shadows in t lungs, migration of the pneumonic process from one lob to another, and the presence of cold agglutinins in titres 1 : 64 or more may form a triad distinguishing one grou of cases from the remainder. That this distinction ma

TABLE III—CLINICAL AND RADIOLOGICAL FINDINGS AND COLD-AGGLUTININ TITRES IN 15 CASES OF MIGRATORY ATYPICAL PNEUMONIA

Case no.	Sex	Age (yr.)	Summary of findings	Cold-agglutinin titre	Type of X-ray picture*	Duration of pyrexia (days)	Durati of illne (days
1	F	23	Began with cough, fever, and pleural pain, with moist sounds at right base and pleural rub at left base. Radiogram showed mottling of right lung. 2 weeks later physical signs and radiogram showed involvement of both bases.	128	C	19	38
8	F	25	Was in contact with case 1 and developed similar symptoms 16 days later. Both bases showed opacities simultaneously, and moist sounds heard bilaterally.	256	C	3	30
10	M	24	First seen on 8th day of disease. Sticky crepitations at right base, but radiogram showed patchy consolidation of right middle and lower zones.	512	C	4	28
11	M	22	Admitted on 8th day of disease. Bronchial breathing and scattered râles over right lower lobe. Impaired breath sounds at left base 2 weeks later. Radiogram showed patchy opacities at both bases on 15th day of illness.	256	C	10	23
12	M	28	Cough, with scanty blood-flecked sputum. Moist sounds first heard at right apex. Râles at right base 3 days later. Radiogram on admission showed partial consolidation of right middle lobe.	128	C	2	10
13	M	30	Admitted on 7th day of disease. Cough, but little sputum. Moist sounds at right lower lobe, with impaired percussion note and breath sounds. Radiogram showed increased striation in left lower zone, with patchy shadowing of right lower and middle zones.	1024	C	2	35
15	M	26	Admitted on 10th day of disease. Cough and slight hæmoptysis, pleural pain, bronchophony, and râles at left base. Râles were heard at right base a week later, and left lower lobe showed signs of consolidation. Radiogram showed dense opacities at both bases, and later bilateral pleural effusion developed. Repatriated to Canada; further progress unknown	128	C	15	[illegible]
0	M	19	Cough and scanty sputum. Râles heard at both bases. Radiogram showed a fairly dense non-homogeneous shadow in right lower zone only, suggestive of partial consolidation.	256	C	nil	27
18	M	18	Cough, with no sputum. Sticky râles at right base, with tubular breathing. Radiogram showed partial consolidation of right lower lobe. Symptoms resolved but relapsed after 2 weeks. Râles heard in right interscapular area, and radiogram showed soft shadows in right upper and middle zones.	64	C	14	120
20	M	29	Admitted on 10th day. Cough and general malaise. Treated with sulphathiazole for 6 days without benefit. Many moist sounds in right base, and diminished air-entry in left base. On 15th day of illness developed a pleural rub with clinical consolidation of right lower lobe. Radiogram on admission suggested atypical pneumonia involving right mid-zone and left lower and middle zones. Leucocytes never exceeded 14,000/c.mm., and no pneumococci cultured from sputum.	256	C	36	80
27	M	33	Admitted on 9th day. Cough and malaise, with slightly bloodstained sputum. Diminished ventilation at left base, with râles at both bases. Radiogram showed patchy shadows in all zones on right side.	256 +	C	6	31
30	M	25	Cough, malaise, slight dyspnœa. Diminished movement at left base, with moist sounds at both bases. Slight pleural rub heard 3 weeks later at right base. Radiogram showed patchy consolidation of both lower lobes.	64	C	20	30
41	M	25	Admitted on 8th day. Cough and pain in right chest. Râles at right lower lobe. Sulphathiazole (40 g.) given with no definite effect. Radiogram showed slightly impaired translucency at right base, with "congestive changes" at left base.	64	C	5	35
51	M	32	Cough and pyrexia. No sputum. Râles at right lower lobe, right apex, and right axilla. Radiogram showed "dense opacity" at right upper zone only.	128	A	3	35
52	F	21	Developed cough and pyrexia while in hospital under treatment for chronic pyelitis. Post-tussive râles over left lower lobe, but radiogram showed irregular mottling of left upper zone, suggesting a resolving atypical pneumonia	128	C	12	21

* Radiological findings classified according to description in table II.

be due to a specific ætiological factor is supported by the seasonal incidence of this type of case and by the closeness of the association between these features in cases known to have a common origin.

SUMMARY

A survey was made of the clinical, pathological, and radiological findings in 51 cases of atypical pneumonia admitted to a R.A.F. hospital between September, 1943, and June, 1945.

In their general characteristics these cases closely resembled each other and those described by other workers. Correlation of cold-agglutinin titres with other features of the disease, however, suggested that some of the cases, presenting the triad of patchy consolidation, migration of the pneumonic process, and cold agglutinins, might have a common and distinct ætiology.

My thanks are due to the Director-General of Medical Services, R.A.F., for permission to publish this paper; to Group-Captain W. A. S. Duck, O.B.E., for permission to collect the necessary material; and to Wing-Commanders F. H. Coleman, A. Nelson-Jones, and D. G. Ferriman for their coöperation in the investigation.

INTRADERMAL REACTION IN TRICHOMONAS INFECTION

S. ADLER
O.B.E., M.B. Leeds, M.R.C.P.
PROFESSOR OF PARASITOLOGY

A. SADOWSKY
M.D. Odessa
LECTURER IN OBSTETRICS AND GYNÆCOLOGY

THE HEBREW UNIVERSITY, JERUSALEM

IT is not difficult to prepare bacteria-free cultures of *Trichomonas vaginalis* by exploiting the bacteriostatic action of sulphonamides and penicillin.[1] With antigens prepared from such cultures we have investigated the question whether vaginal infection with *T. vaginalis* produces any detectable immunological reaction in the host.

Preparation of Antigen.—Rich cultures of liver slant overlaid with Trussel Johnson's fluid medium adjusted to pH 6 are used. Inactivated calf serum 10% is used instead of human serum.

The cultures are washed by centrifuging three times in saline, and the number of flagellates per c.cm. in a suspension of saline is determined by counting in a hæmocytometer.

The suspension of flagellates is again centrifuged, and distilled water is substituted for the saline in quantities sufficient to produce 2,000,000 flagellates per c.cm. The suspension is next allowed to stand overnight in the ice chest and is then centrifuged.

The supernatant fluid is next added to an equal amount of 1% solution of phenol in distilled water, so that the final product is an aqueous extract of 1,000,000 flagellates per c.cm. and 0·5% phenol. This is used for the intradermal tests.

Method of Testing.—The tests were carried out on outpatients. For each intradermal test (on the forearm) 0·1 c.cm. of the antigen is used, and 0·5% solution of phenol is used as a control. The patients were observed for half an hour after the injection, and in no case was any difference noted then between the sites inoculated with antigen and the control sites. They were re-examined after 24 hours and after 48 hours, and some of them subsequently.

The site inoculated with the antigen was compared with the control site, and a reaction was considered positive if there was an area of very definite redness round the site of inoculation and the control was completely negative.

Results.—The area of redness varied from 1 to 2 cm., and in three refractory cases was 5 cm. in diameter. The reaction in most cases began to fade after 48 hours, but in nine cases the reaction was still positive after 48 hours, and in one case after 72 hours. In one case a second inoculation with antigen caused a severe reaction; the patient complained of malaise and was confined to bed for 2 days.

In 59 cases in which *T. vaginalis* was not found on microscopical examination, 45 gave a negative, 7 a positive, and 7 an indefinite skin reaction. Of the 7 which gave a positive reaction one was reinvestigated and found positive on microscopical examination, and another was again found negative. The remaining 5 patients did not return for re-examination. Of this series (excluding the case which was subsequently found positive on microscopical examination) 77% therefore gave a negative reaction.

In 43 cases proved positive by microscopical examination, 35 gave a positive, 2 a negative, and 6 an indefinite skin reaction. Thus 81% in which flagellates were found on microscopical examination gave a positive skin test.

In 23 cases, 12 negative and 11 positive on microscopical examination, the reactions produced by an aqueous extract of 2,000,000 flagellates per c.cm. were compared with those produced by the extract of 1,000,000 flagellates per c.cm. As a result of these tests 3 cases (2 negative and 1 positive on microscopical examination) which had not reacted to the extract of 1,000,000 flagellates per c.cm. gave a positive reaction to the extract of 2,000,000 flagellates per c.cm.; 2 cases (1 positive and 1 negative on microscopical examination) which had given an indefinite reaction to the extract of 1,000,000 flagellates per c.cm. gave a positive reaction to the extract of 2,000,000 flagellates per c.cm.; and 2 cases negative on microscopical examination did not react to either extract.

In one case positive to both extracts the erythema disappeared after 48 hours from the site inoculated with the extract of 2,000,000 flagellates per c.cm. but persisted in the site inoculated with the extract of 1,000,000 flagellates per c.cm.

In 15 of the cases (8 positive and 7 negative on microscopical examination) there was no difference in the results obtained with the two extracts. In 7 other cases negative on microscopical examination antigen was inoculated simultaneously into two sites with identical (negative) results.

It seems that there is no important difference in the results obtained with aqueous extracts of 1,000,000 and of 2,000,000 flagellates per c.cm.

Discussion.—Obviously the use of the skin test for diagnostic purposes is not to be recommended since direct microscopical examination gives better results. In only one case did we detect by the skin reaction an infection which was not revealed by the first microscopical examination. But it is of interest to note that in about

---

[1] Adler, S., Pulvertaft, R. J. V. *Ann. trop. Med. Parasit.* 1944, 38, 183.

80% of cases of infection with *T. vaginalis*, which produces a local infection, antigen is absorbed in amounts sufficient to produce a specific sensitisation; and about the same percentage of women with negative microscopical findings give a negative skin reaction. In our series we have not noted a correlation between the severity of the clinical condition and the skin reaction, but this point remains to be investigated further.

SUMMARY

In 35 out of 43 women with a vaginal infection with *Trichomonas vaginalis* a skin test 24 hours after intradermal inoculation with 0·1 c.cm. of an aqueous extract of 1,000,000 (and in some cases of 2,000,000) flagellates per c.cm. gave a positive reaction.

In 45 out of 58 women negative on microscopical examination there was no reaction.

Antigen of *T. vaginalis* is absorbed through the wall of the vagina.

We are grateful to Miss Alexandra Polyakoff for help in recording skin reactions and following up cases.

URTICARIAL REACTIONS TO INTRAMUSCULAR PENICILLIN

A REPORT OF FOUR CASES

L. STEINGOLD

M.B. Glasg.

ASSISTANT PATHOLOGIST, EMERGENCY PATHOLOGICAL SERVICES

URTICARIA is the commonest delayed reaction to intramuscular penicillin (Haswell and Wilkinson 1946, Gordon 1946, Barker 1945, Criep 1944, Stokes et al. 1944, Moore et al. 1944). It is doubtful, however, whether penicillin or some impurity is the responsible agent. When a supply of pure penicillin became available at Horton Emergency Hospital this point was investigated.

INVESTIGATION

Four patients were selected who had previously shown urticarial reactions, and intradermal tests were performed on each with three batches of penicillin: (1) penicillin X, generally used in the hospital; (2) penicillin Y, from a different source and not in general use here; and (3) pure penicillin. The penicillin contents of these products were 1420, 450, and 1666 units per mg. respectively. They were made up, on label values, in a strength of 1000 units per c.cm. in normal saline. The preparations were tested simultaneously, by intradermal injection of 0·05 c.cm. into the volar aspect of the arm and forearm.

An immediate slight red flush round the site of injection was noted with all three preparations. This lasted a minute or so only and was thought to be traumatic. In negative tests there was no further reaction. In positive tests it was followed in about ten minutes by the appearance of a mottled red area 8–12 cm. in diameter, round the injection weal. The weal became very white, tense, and slightly enlarged. This appearance persisted at least an hour and was associated with local itching.

Case 1.—A man, aged 23, with pulmonary tuberculosis, had had a two-stage thoracoplasty, with a course of penicillin after each stage. The first course consisted in three-hourly intramuscular injections of 20,000 units each. Three doses were given on the first day, and eight each day thereafter for a further seven days. On the seventh day of this course a giant urticarial rash appeared on the patient's back. This spread rapidly till it covered his whole body except face, palms, and soles. There were intense itching and some malaise. There was a favourable response to subcutaneous adrenaline in two days. The second course began twenty-one days after the beginning of the first. Four doses of 20,000 units were given on the first day, and eight of 15,000 units on each of two subsequent days. On the last of these three days the urticaria recurred. Penicillin was discon and with subcutaneous adrenaline the condition re

The penicillin administered in this and the foll cases was freshly made up in sterile normal saline, 5 containing 100,000 units.

The patient gave no personal or family history of a phenomena. He had had a course of intramuscular pe in India a year previously. No details were availabl he thought that an American product had been used had developed no allergic reaction on that occasion.

His skin reactions were tested twenty days after th appearance of his urticaria, and again twenty-one days with identical results, except that dermatographia wa noted.

Case 2.—A man, aged 36, with furunculosis, was t with intramuscular penicillin. He received forty inje of 25,000 units in six days.

Next day, the seventh after the start of his treatme developed a giant urticaria, with intense itching. rapidly spread from his back and buttocks to cover hi and whole body except palms and soles. The con responded in a day or two to subcutaneous adrenaline.

The patient stated that he had for some years been s to mild recurrent attacks of urticaria, which he attribut certain foods, such as shellfish. He gave no family hi of allergy and had never had penicillin before.

His skin reactions were tested twenty days after the appearance of his urticaria, and again twenty-one days with no change in the results.

Case 3.—A man, aged 56, with lung abscess, was gi course of intramuscular penicillin. On the first da received one dose of 20,000 units. On each of the subse seven days he received eight doses of 30,000 units. O eighth day of the course he developed a giant urticaria lower back and buttocks. His course of treatment completed that day, and the rash did not spread. There however, intense itching. The reaction responded fa ably to subcutaneous adrenaline. The patient gav personal or family history of allergy and had never penicillin before.

His skin reactions were tested once only, sixteen days the first appearance of his urticaria.

Case 4.—A man, aged 28, with pulmonary tubercu had had a course of intramuscular penicillin in another pital about three weeks before admission here. The re of this course were not available, but the patient, who intelligent and coöperative, stated that he had had 10 units a day for eight days. On the seventh day he developed a blotchy red rash all over his body. There been intense itching and considerable malaise. He gav personal or family history of allergy and had never penicillin before.

His skin reactions were tested once only, about tw three days after the first appearance of his rash.

The results of the skin tests on these patients shown in the table.

INTRADERMAL TESTS ON PATIENTS SHOWING URTICARIA A PENICILLIN

Case	Penicillin X	Penicillin Y	Pure penicil
1	+	+	0
2	+	+	0
3	+	+	0
4	+	+	0

0 = no reaction. + = positive reaction.

Control observations were carried out on allergic non-allergic subjects who had never had penicillin having had it, had shown no untoward reaction to They may be divided into three groups:

I.—Five medical students aged 22–35. All were heal none had had penicillin before, and none gave a person family history of allergy.

II.—Four patients who had had penicillin 12–32 d previously without reaction. They gave no personal family history of allergy. Two had had thoracoplasty pulmonary tuberculosis, one a partial gastrectomy chopneumonia, and one a repair of inguinal hernia. The ge of penicillin given varied from 160,000 units a day for e days to 240,000 units a day for ten days.

III.—Five allergic subjects. Only one had ever had icillin. All were cases of bronchial asthma, with eosinoilia ranging from 4·8% of 8400 white cells per c.mm. to 2% of 34,000 white cells per c.mm. One patient had had urse of 160,000 units of penicillin a day for four days for ipelas two years previously, without reaction. She had d bronchial asthma for about six years.

None of the subjects in any of these three control ups showed any reaction to either of the commercial icillin preparations or to pure penicillin.

DISCUSSION

Most attempts to determine whether penicillin or purities have been responsible for untoward reactions ve been made in conditions other than penicillin ticaria (Bedford 1946, Barker 1945, Pyle and Rattner 44, Goldman et al. 1946. Silvers 1944). Two investigaons in cases of urticaria may be mentioned.

Barker (1945) describes two reactions, one of which was an ticaria developing four or five days after the start of penicillin tment. He tested his patient's skin reactions to comcial penicillin before and after autoclaving. His patient wed a positive reaction to the untreated preparation and o reaction to the autoclaved preparation. Barker deduced at the reaction was due to penicillin, though it appears sible that autoclaving destroyed not only the penicillin t also some at least of the impurities.

Criep's (1944) patient received a fourteen-day course without reaction; but, when a second course was begun ten days ter, there was an immediate massive generalised urticaria, hich persisted for the seven days of this second course. Criep formed intradermal tests on his patient with penicillin, icillium extracts, and a mixture approximating to the dium used in the preparation of penicillin. He obtained a sitive reaction to commercial penicillin, and no reaction o either of the others.

All of the present series of patients showing penicillin ticaria are males. There is an impression in this spital that reactions are commoner in males than in males, and most of the reactions recorded elsewhere ve been in males.

All the reactions were similar, consisting in a giant rticaria beginning on the back within seven or eight ys of the start of treatment, irrespective of the dosage f penicillin. Thus, case 1 received 160,000 units a day, se 2 had 200,000 units a day, and case 3 had 240,000 its a day. The urticaria was associated with intense ching and responded fairly rapidly to subcutaneous drenaline in the three cases in which it was tried.

All the cases showed positive skin tests with two ands of commercial penicillin but not with pure nicillin.

In the controls, which included normal subjects and bjects showing allergic phenomena, who had not had nicillin or had had it without reaction, no skin sitivity to any of these preparations was demonrated. This reaction therefore appears to be an llergic response to an impurity in commercial penicillin, hich is not specific to any one brand and is not eradicated y commercial purification of the preparation to 1420 its per mg., though this may give a lesser incidence.

Criep's (1944) observations suggest that the responsible purity is not a normal constituent of the medium sed in the preparation of penicillin, nor of *Penicillium tatum* itself, but that it is a metabolic or similar oduct produced during the growth of the mould. His case, however, showed urticaria twenty-four days after the start of penicillin therapy, as opposed to seven r eight days in this series.

The results of repeating the skin tests on cases 1 and 2 appear to indicate that the allergic state induced by commercial penicillin persists at least six weeks after its first appearance.

DERMATOGRAPHIA

Skin tests were repeated on case 1 three weeks after they were first performed. His sensitivity to the commercial products had persisted, and the immediate traumatic reaction to all three penicillin preparations was severe and persisted half an hour. It was also noted that, unless the preparation of the skin with spirit was done very lightly, it was followed by deep reddening of the area treated. The patient's back was then scratched lightly with a needle. This produced the typical exaggerated weal and flare of dermatographia. The patient was surprised to find that moderate friction of his skin caused the appearance of bruising, and said he had never noted this before. When his skin reactions had been tested previously no such severe response to friction or to intradermal injection had been observed, but it cannot be stated unequivocally that he had not had dermatographia at that time. Dermatographia was also seen by Barker (1945) in his urticarial case, and by the doctor in charge of case 2, during the attack of urticaria, although it could not be elicited at the time of either of his skin tests. It therefore appears to have been a temporary condition in case 2.

SUMMARY

In 4 cases intramuscular penicillin caused urticaria. The results of intradermal tests with pure and commercial penicillin suggest that this was an allergic response to an impurity in the commercial preparations. Controls showed no skin sensitivity to any of the penicillin preparations. In 2 of the cases dermatographia was observed.

I would like to thank Dr. E. H. Creed, sector pathologist, Emergency Pathological Services, for his advice in the compilation of this paper; Prof. Arnold Sorsby, for supplying me with pure penicillin; and the members of the staff of Horton Emergency Hospital who made their cases available to me.

POST-TRAUMATIC FISTULA OF PANCREAS

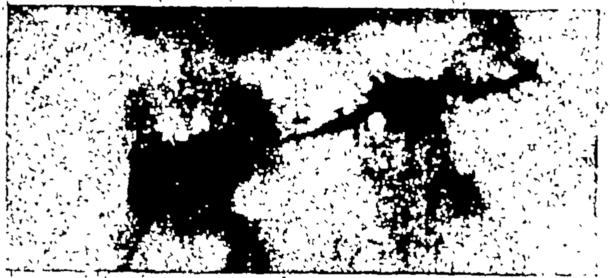
SUCCESSFULLY TREATED BY SURGERY

GEOFFREY FLAVELL
F.R.C.S., M.R.C.P.
LATE WING-COMMANDER, SURGICAL SPECIALIST, R.A.F.V.R.

THE vast majority of persistent pancreatic fistulæ follow marsupialisation of pseudopancreatic cysts. Those which result from direct trauma are almost always due either to damage done during a surgical operation, such as gastrectomy (Biancheri 1940) and duodenal resection (Zinninger 1942), or to penetrating wounds of the abdomen, usually gunshot wounds and usually involving trauma to some other organ. The case recorded here belongs to the remarkably rare group where trauma was direct, did not penetrate, and affected the pancreas exclusively. I have been unable to find a similar injury recorded.

In the operation of choice, which was used in the present case, the fistula is implanted into some portion of the alimentary tract (Lahey and Lium 1937). There are several modifications. Thus, 15 of the 27 published cases were performed as pancreaticogastrostomies, 10 as pancreaticojejunostomies, 1 as a pancreaticocholecystostomy, and 1 as a pancreaticocholecystostomy followed by a cholecystogastrostomy. Holbaum's (1927) was the only fatal case. The surgical technique is well described by McCaughan and Sinner (1937) and McCaughan and Purcell (1941).

The non-surgical treatment of pancreatic fistulæ dates back to Claude Bernard, who tried to close them by inducing pancreatic "atrophy" with olive-oil injections into the sinus. The effect of these in diminishing secretion was probably due to digestion of the oil, causing blockage of the fistula by soapy deposit. A similar state of affairs arose in the present case when 'Neo-Hydriol' was used to delineate the fistula.



Radiogram showing pancreatic fistula communicating with main duct of tail of pancreas.

Lahey and Lium (1937) found experimentally that pancreatic secretion was stimulated by taking food (especially carbohydrate), by drinking water, and particularly by highly acid gastric secretion. A diet of carbohydrate 328 g., protein 102 g., and fat 134 g. produced a daily flow of 550 c.cm. of pancreatic juice (collected from a tube passed into the fistula); while sodium bicarbonate gr. 30 and calcium carbonate gr. 30 given hourly, with atropine gr. $^{1}/_{150}$ t.d.s., reduced the amount of secretion to 387 c.cm. The relatively high proportion of carbohydrate was justified by its easy assimilability as opposed to fat or protein. The effect of atropine alone, even in toxic doses, was negligible.

On the other hand, Wohlgemuth (1907) advocated a low-carbohydrate diet (since carbohydrate appears to stimulate secretion) with high fat and high protein, supplemented with alkalis. This régime produces a definite fall in secretion and is of value in reducing a large fistula to convenient proportions for operation.

Among the many non-effective measures which have been tried for closing persistent fistulæ may be mentioned the application of local caustics, the administration of 'Ereptone' and of atropine, and the use of radium or deep X rays. All are useless.

The fistulæ encountered in practice are always partial, since a total pancreatic fistula does not appear to be compatible with life. McCaughan and Elman (1927) have shown that a total fistula in dogs leads to death in 5–8 days, and the same seems to hold good in man.

CASE-RECORD

A healthy flight-sergeant, aged 28, riding a bicycle at night on August 11, 1942, with an electric torch thrust inside his shirt, fell off, and the torch was forced against his upper abdomen. He was taken to hospital with spasmodic attacks of severe epigastric pain accompanied by vomiting, and was found to have moderate rigidity of his upper abdomen, with tenderness over the right colic gutter. His temperature was normal and his pulse-rate 72 per min.

A laparotomy was performed the same night, through a right upper paramedian incision. The gastrocolic omentum was found to be infiltrated with blood and the lesser omentum to be torn for about 4 in. Blood-clot and an area of fat-necrosis were present in the lesser sac, and the pancreas was seen to be ruptured at the junction of head and body. No other viscus was damaged in any way. A bleeding area in the ruptured pancreas having been ligated, the whole site was drained and the abdomen closed. The patient made a reasonably uneventful recovery from this operation. Clear pancreatic continued to drain from his abdominal wound at the about 400 c.cm. per 24 hours.

On Nov. 3 he complained of abdominal discomfort, and fistula was seen to be dry. He vomited once or twice. examination a cystic swelling was palpable in the epigas so the abdomen was reopened through a *transverse* in which included the fistula and divided the left rectus m A cyst was opened near the greater curvature of the s and found to contain about half a pint of turbid fluid. was evacuated, and the cyst wall was swabbed with formalin. A gauze pack was inserted and the wound c A Wangensteen régime, with duodenal intubation, adopted, and the patient made a good recovery. This portion of his treatment and the first two operations carried out in Malta by Lieut.-Colonel H. S. Shucksmith.

On Nov. 14 the patient's condition was sufficiently good him to be transferred to England. On arrival here, his ab nal wounds were well healed, except for a small fistula drained at the junction of the vertical and transverse inc From it *flowed a clear* pancreatic juice, which had se excoriated the surrounding skin in spite of zinc-oxide dr There was no abnormality of his stools, either in colour composition. No neutral fat, soap plaques, or fatty crystals were seen. His diastatic index was 60, and his output of diastase 204,360 units. The fasting blood-sugar 95 mg. per 100 c.cm., and his glucose tolerance was no The specific gravity of the secretion was about 1·012.

The fistula was gently dilated with filiform gum-el bougies until it would accommodate a no. 4 soft ru catheter, which was passed up the track for about 4 in. was then led *to a bottle strapped to the patient's* thigh, all secretion collected was fed back by mouth, mixed f palatably with his food. The flow of juice remained a *400 c.cm. per 24 hours, and the excoriation of the skin* rap disappeared after the secretion had been diverted to collecting flask. Radiography after 5 c.cm. of neo-hyd had been injected through the catheter outlined a nar track passing upwards, backwards, and to the left, and end in what was clearly the main duct of the pancreatic tail w numerous short wide branches (see figure).

On Dec. 8 an operation for the closure of the fistula carried out by Air Vice-Marshal Geoffrey Keynes, using Lahey technique. The vertical incision was reopened, toget with a few inches of the transverse, the track itself be excluded. The track was then pared out, with considera difficulty, from the dense fibrous tissue in which it embedded, and was found to run between the stomach *transverse colon—i.e.,* through the gastrocolic omentum to the region of the junction of pancreatic body and tail.

During this process the track, along which a no. 6 rubber catheter had been passed as a guide, was *accident* opened. The tear having been sutured over, and the wh fistulous track pared down to convenient dimensions, a lo of the proximal jejunum was approximated to the *distal* e of the track. A purse-string suture was then inserted on antimesenteric border, which was secured by four *Allis force*

Through this prepared arena, a pair of mosquito force was thrust, and the opening into the bowel lumen was gen enlarged until it would accommodate the track. The appro mation was made by passing two running sutures through t distal end of the track, leading them through the hole in t jejunal wall into the bowel lumen, and out again on each si of the mesenteric attachment, each suture end being separate threaded on an intestinal needle.

By *these four guy ropes* the track was introduced into t jejunum, and the junction secured by interrupted catg sutures round the proximal neck of the track and the jejun orifice. The purse-string suture was *also* drawn tight, and few more interrupted sutures were inserted outside this f additional security. The rubber catheter had previously be cut short flush with the end *of the fistula, and the* remaini portion left in situ to secure the fistulous lumen from occlusio

The guide sutures were then withdrawn, the gastrocol omentum repaired, and the abdomen *closed* in *a* single laye A corrugated rubber drain was left to safeguard the area anastomosis.

For the next four days the patient *was* treated with intra venous glucose saline and continuous duodenal aspiratio At first there was a good deal of pancreatic leakage, but th diminished after the *removal of the* drain, and subside altogether at the end of a week. The patient has since mad an uninterrupted recovery, except for occasional mild nause nd some attacks of aching between the shoulder blades. The bdomen is well healed, and his fistula has been eradicated.

BILATERAL PNEUMOTHORAX AFTER PARTIAL THYROIDECTOMY

B. R. BILLIMORIA
F.R.C.S.
URGICAL REGISTRAR, THORACIC SURGICAL UNIT, HAREFIELD E.M.S. HOSPITAL

ACCIDENTAL injury to the apical pleura is a recognised omplication of thyroidectomy, but injury on both sides, s in the following case, must be unusual. Sir Thomas Dunhill and the late Mr. C. A. Joll had never encountered a similar complication in their own practice.

A man, aged 44, was admitted to hospital with a non-toxic goitre. Radiography of the chest before operation showed no abnormality of the lung fields.

A partial thyroidectomy was done under rectal bromethol, followed by gas and oxygen. No form of pressure anæsthesia was used. Small retrosternal extensions were present on both sides, but no particular difficulty was encountered during the operation. Some bubbling in the depths of the wound was noted, but there was no hiss of air or any suggestion of entry into the pleura. The anæsthetist noticed that the patient's breathing was laboured towards the end of the operation.

On his return to the ward the patient's pulse-rate was unduly raised, and there was respiratory distress. A tentative diagnosis of collapse of the right lower lobe was made. The patient's condition continued to deteriorate. Four hours after operation there was definite surgical emphysema of the neck and well-marked cyanosis. There was increased resonance over the right lung, with diminished air entry over all the lung fields, particularly on the right. The difference in the physical signs on the two sides was slight and was obscured by many adventitious sounds. A provisional diagnosis of a right tension pneumothorax was now made.

Radiography of the chest showed a bilateral pneumothorax, more pronounced on the right side, with collapse of the right upper lobe. The left pneumothorax had not been suspected clinically.

Intrapleural pressures were found to be +15 to −10 mm. Hg on both sides. A total of 4000 c.cm. of air was withdrawn from the right side and 1500 c.cm. from the left, but this gave little relief. It was concluded that the small tube draining the incision in the neck was maintaining the pneumothorax. The tube was removed and the wound firmly strapped. The pleural pressures were then stabilised on the negative side, and the man's general condition improved considerably. Next day a further 250 c.cm. of air was withdrawn from the right pleural space.

Apart from gross subcutaneous emphysema and a transient atelectasis of the right lower lobe, the patient made a remarkably good recovery. He was discharged nine weeks after the operation. Radiologically, the lungs had re-expanded and the fields were clear.

The main interest of this case lies in the difficulty of diagnosis. During the operation nothing unusual, such as a sudden hiss of air, was observed which might have led one to expect a pneumothorax. Postoperatively the diagnosis could not be made on the physical signs, and if the patient had died the true state of affairs might not have been appreciated even at necropsy. The diagnosis could finally be established only by radiography.

It seems, therefore, that in all patients developing acute respiratory distress after thyroidectomy—or indeed after any operation where the field approaches the pleura, as in cervical sympathectomy—the possibility of a tension pneumothorax should be investigated by radiography of the chest.

I wish to thank Mr. David Levi, Prof. G. W. Pickering, Mr. T. Holmes Sellors, and Dr. K. Stokes for permission to report this case.

Reviews of Books

Recent Advances in Clinical Pathology

Editor: S. C. DYKE, D.M. Oxfd, F.R.C.P., pathologist, Royal Hospital, Wolverhampton. London: J. & A. Churchill. 1947. Pp. 468. 25s.

THIS book, by a group of recognised authorities, will be found more often on the bench of the hospital pathologist than behind the glass door of his book-case; it will also appeal to the physician and surgeon. The articles on atypical pneumonia, anaerobic infections, Rh factor, blood-chemistry in gastro-intestinal disease, and analysis of semen all illustrate the growing importance of clinical pathology. Histology, a subject often regarded as having achieved finality, is discussed in a well-illustrated chapter, and the biopsy techniques now in vogue are set out: a statistical analysis is included of material collected over a period of six years in the Oxford Lymph Node Registry.

The book owes its origin to the European Association of Clinical Pathologists, a body of men and women who during the war years worked in our midst. Some of them, now back in their homes, have sent over their contributions to this record of the present state of the knowledge and practice of clinical pathology in Britain.

Biochemistry of Cancer

JESSE P. GREENSTEIN, head biochemist, National Cancer Institute, Bethesda, Maryland. New York: Academic Press. 1947. Pp. 389. $7.80.

THIS monograph, which the author has tried to make intelligible rather than comprehensive, is the most satisfactory account so far published of the recent biochemical phase of cancer research. Early in this century experimental pathologists established the fundamental research techniques and methods. Their work revealed the biological nature of malignant growth and opened the way for advances by biochemists, chemists, and geneticists. The greater part of the book sets out the knowledge of the biochemistry of cancer gained during the last twenty years. After describing general properties of animal tumours, Dr. Greenstein discusses the induction of cancer, summarising the research which led to the isolation and synthesis of carcinogenic compounds. Although several hundred different carcinogenic substances are known to induce a large variety of growths in different species and strains of animals, the mechanism of the carcinomatous change is still obscure. We still do not know whether carcinogens merely hasten the appearance of tumours which would normally arise spontaneously or whether they are the sole cause of the malignant transformation. The intrinsic factors in carcinogenesis include the sex hormones, such agents as the milk factor or mammary-tumour inciter, the genetic constitution of the host, viruses, and other less well defined non-specific endogenous carcinogens. The influence of hormones, and of nutrition and chemotherapy, is considered in the section on attempts at control of tumour induction and tumour growth.

Dr. Greenstein's own researches on cancer have been mostly on the comparative enzymology of normal and malignant tissues, and he describes this work in the section on the properties of tumours—the longest and best section in the book. One of the difficulties in this kind of work is to decide with which tissue the malignant growth can be compared. The most extensive and most reasonable comparisons have been made between hepatomata and normal adult, regenerating, and fœtal liver. No evidence of a specific constituent of cancer cells has ever been found. Malignant cells differ from normal cells not in the kind of their enzymes or other components but rather in their relative amount or activity. Tumours of all types and all species resemble each other chemically more than they do normal tissues, or than normal tissues resemble each other. Some tumours contain specific enzyme systems which are vestiges of the tissue of origin, but these tend to be lost on transplantation or on natural spread of the tumour to other parts of the body; the metastases of primary tumours resemble each other even more closely in their chemical properties than do the original primary tumours.

No less important than the properties of tumours are the changes which the tumour induces in the host. Dr. Greenstein makes no attempt to deal with the mass of empirical work which has been devoted to the search for a diagnostic test for cancer. One of the outstanding changes seen in tumour-bearing animals is the reversible reduction in liver catalase. Other changes are a fall in serum proteins and hæmoglobin, an increase in plasma enzymes such as zymohexase in rats with large tumours, of alkaline phosphatase in cases of some bone tumours, and of acid phosphatase in cases of prostatic carcinoma. Recent American work suggests that the pattern of α-keto steroids in the urine is changed in some forms of cancer (in addition to tumours of the adrenal), and these changes may ultimately be of value for the diagnosis of cancer.

In discussing the present status of the cancer problem, Dr. Greenstein says: "By and large, one of the principal hopes of the control of cancer lies fundamentally in a knowledge of the chemical nature of the malignant cell, and in successful development of chemotherapeutic approaches which must depend upon this knowledge. The fact that cancer tissues appear to have a nearly similar chemical pattern offers some hope and encouragement in their study."

Renal Hypertension

Eduardo Braun-Menendez; Juan Carlos Fasciolo; Luis F. Leloir; Juan M. Munoz; Alberto C. Taquini. Translated by Lewis Dexter, M.D. Springfield, Ill.: C. C. Thomas. London: Baillière. 1946. Pp. 451. 37*s.* 6*d.*

This monograph, by a group of men whose studies have contributed so largely to the illumination of the problem of renal hypertension, is lucidly written, and the English text bears no sign of translation. While the conclusions on human hypertension of various sorts have a humoral leaning, conflicting views are well discussed, and each of the 18 chapters carries a short, critical, and (considering the controversial nature of the subject) remarkably well-balanced summary. An appendix gives details of technical and experimental procedures.

Gynecological and Obstetrical Pathology

(2nd ed.) Emil Novak, M.D., F.A.C.S., associate in gynecology, Johns Hopkins Medical School. London: W. B. Saunders. 1947. Pp. 570. 37*s.* 6*d.*

This book deals systematically with the naked-eye and microscopic appearances of pathological conditions of the female reproductive tract, and to a lesser extent with pathological conditions of pregnancy. It is written for the clinician, showing how essential it is for him to have a thorough knowledge of the pathology of the conditions he is called upon to treat, if his judgment is to be sound and his treatment rational. Normal histology and physiology is described first so that deviations from the normal can be readily appreciated. The work is balanced but also comprehensive, even rare conditions being adequately described. Gynæcological lesions are particularly well covered, but it seems a pity that many of the pathological lesions of pregnancy, occurring in the kidney, liver, brain, and other organs, are not included.

The work is profusely illustrated with photomicrographs and photographs, some of them in colour; over a hundred new illustrations have been added in this new edition.

Principles and Practice of Tropical Medicine

L. Everard Napier, C.I.E., F.R.C.P., consultant to the Secretary of War, formerly director and professor of tropical medicine, Calcutta School of Tropical Medicine. New York and London: Macmillan. 1946. Pp. 917. 35*s.*

This new textbook is founded on a smaller volume published privately by Lieut.-Colonel Napier in India. It is a textbook on the so-called tropical diseases, and not an encyclopædia of tropical medicine. The various conditions are systematically dealt with in a manner particularly applicable to the student and non-specialist practitioner, and to these this volume should afford essential information in a clear and concise form. The book is liberally illustrated, though the standard of production falls below what is customary in works published in the United States. Under the h of malaria, much space is devoted to the use of q and a lesser amount to mepacrine and pamaquin, no reference is made to the newer and more synthetic antimalarials. Again, in the treatment amœbiasis the specific treatment of an associated subsequent bacillary colitis with the sulpho preparations or penicillin finds no place; and in that the spirochætoses, although penicillin is referred to specific in relapsing fever it is not mentioned in nexion with yaws. Many of the addenda to the v chapters were brought up to date in 1944 and perhaps have been incorporated in the text. Th however, are not serious matters. Colonel Napier provided a thoroughly practical textbook on its subj

A Manual of Tomography

M. Weinbren, B.SC., M.R.C.S., F.F.R., radiologist, Ch of Mines Hospital, Johannesburg. London: H. Lewis. 1946. Pp. 270. 15*s.*

This monograph is a good survey of tomogra based on seven years' extensive use of the me The section on the lungs, with good illustrations cavities and tumours, is followed by an outstan chapter on coarctation of the aorta, with unique pict of angiocardiography and tomography combined.

The longest section of the book deals with the sp a region where tomography is seldom employed in country. Dr. Weinbren has a very wide experience spinal injuries in the Rand miners and proves t tomography reveals many fractures invisible in strai radiograms. This section is worthy of close stud by orthopædic surgeons as well as radiologists, suggesting as it does a more extensive use for tomography in medico-legal cases. Dr. Weinbren's enthusiasm for his subject is shown by his tomographic investigations of such diverse regions as the nasal sinuses, the kidneys, and the gall-bladder; and though he does not advocate it as a routine in these regions, he shows that it can be of great help in difficult cases.

Student's Handbook of Surgical Operations (8th ed. London: Cassell. 1946. Pp. 574. 15*s.*).—Sir Cecil Wakeley, in his latest revision of this well-known handbook, has included some new operations on the chest and heart, and has added 50 new illustrations. The book remains a useful summary for the examination candidate.

Chemical Constitution of Natural Fats (2nd London: Chapman & Hall. 1947. Pp. 554. 45*s.*).—Prof. T. P. Hilditch's notable monograph has put on weight. Despite the frustrations of war, study of the fats has gone on, mainly perhaps in the United States and India, but also in England, Holland, and France; "at all events," he says in the preface, "a great deal of new matter has appeared during the six or seven years which have elapsed between the two editions of this book." He includes among the more striking advances many new facts about component acids in the groups of land-animal and vegetable fats, new data on seed fats and on depot fats in man and in a wider range of wild animals, recent work on component glycerides, and much fresh information on fatty acids. The chapter on experimental technique has been revised and expanded, and the indexing has been rearranged.

Allgemeine Neurosenlehre (2nd ed. Basle: Schwabe. 1946. Pp. 518. Sw. fr. 32.).—The author of this work, Prof. Rudolf Brun, is a psycho-analyst, but with a difference: like his teacher, August Forel, he has occupied himself with the behaviour of ants as well as of men. His entomological studies led him in 1920 to examine closely what we mean by instinct, and in 1926 to state the biological parallels which exist between conflict, as understood in the Freudian theory, and the instinctual conflicts that may be manifested in ants and other animals. This psychobiological theme runs prominently through the 22 lectures here reproduced, and gives them an individuality which distinguishes them from the general run of psycho-analytic formulations of the causes and pathology of neurotic illness. Although the author pays very little attention to recent work on the psychology of animals, yet the effort at synthesis between biology and psychology, and the incorporation of much of von Monakow's teaching make the book a useful contribution to a well-worn subject.

TRADE MARK

'S.V.C.'

BRAND

acetarsol vaginal compound

Supplies:

tablets,
containers of 25, 100 and 500

powder,
containers of 6 Gm. in packets of 6
500 Gm.

The high incidence of pathogenic protozoal infection in leucorrhoea justifies the use of 'S.V.C.' in most cases of this condition met with in general practice.

'S.V.C.' contains acetarsol combined with a suitable carbohydrate for promoting the growth of Doederlein's bacillus.

The product is available in effervescent tablets for insertion and in powder for insufflation.

manufactured by

MAY & BAKER LTD

distributors

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD. DAGENHAM

An anti-allergic and anti-spasmodic agent

'Benadryl'

'Benadryl' is an anti-histamine agent possessing both anti-allergic and anti-spasmodic activity.

The most striking results reported are in the treatment of hayfever, urticaria, vaso-motor rhinitis and angio-neurotic œdema. It has been successfully used in serum reactions, drug sensitization, penicillin reactions and in various allergic dermatoses such as contact dermatitis, atopic eczema and erythema multiforme. There have been favourable responses in many cases of asthma and migraine.

PACKAGES: 'Benadryl' is issued in bottles of 50 capsules, each containing 50 mgm, and as an elixir in bottles of 4 and 16 fl. ounces containing 10 mgm. per 4 c.c. (1 fl. drachm).

Further details will be supplied on request

Vitamin Therapy—its uses and limitations

BETTER NEWS ABOUT BEMAX

Increased supplies of Bemax now being sent to Chemists should ensure that prescriptions will again be met in full. There will also be more Bemax for the priority classes, *i.e.*, expectant and nursing mothers, children and the aged, with perhaps a little left over for the ordinary consumer.

Further, the new Bemax tablets are now available and have been warmly welcomed. Containing 50 per cent. Bemax, they are a vitamin B supplement with uses similar to Bemax itself and the recommended dose provides 200 i.u. B_1—approximately the same as the daily dose of Bemax. The tablets are very palatable and are intended to be chewed.

Doctors are invited to write for a complimentary carton so that they may test the tablets for themselves.

BEMAX Stabilised cereal embryo

1 oz. of Bemax provides approximately :—

Vitamin B1	0.45 mg.	Vitamin E	8.0 mg.	Available Carbohydrate	39%
Vitamin B2 (Riboflavine)	0.3 mg.	Manganese	4.0 mg.	Fibre	2%
		Iron	2.7 mg.	Calorific Value	104
Nicotinic Acid	1.7 mg.	Copper	0.45 mg.		
Vitamin B6	0.45 mg.	Protein	30%		

A *SINGLE* SUPPLEMENT FOR SAFER PREGNANCY

Adequate safeguards against the hazards of pregnancy are now routine in practice. Among these, the provision of priority supplies of essential foods to pregnant women has had a significant effect in reducing maternal and infant mortality. Cases still occur, however, in which full advantage is not taken of these allowances. Where patients are found to be anæmic, debilitated or showing signs of subnormality in respect of the protective factors, the simplest prescription for ensuring an adequate intake of all the necessary nutrients is that of

PREGNAVITE

The recommended daily dose provides:

vitamin A	4,000 i.u.	vitamin E	1 mg.	iodine	not less than 10 p.p.m. each
vitamin D	300 i.u.	nicotinamide	25 mg.	manganese	
vitamin B_1	0.6 mg.	calcium	160 mg.	copper	
vitamin C	20 mg.	iron	68 mg.

Cardiology as a Specialty

THE Royal College of Physicians has published e report of its committee on cardiology,[1] appointed st summer. Of the four terms of reference, the first as the training of cardiologists. A six-year minimum suggested, comprising a year as resident, of which x months should be in a house-physicianship; o years as registrar or the equivalent, in general edicine, with part of that time spent in a laboratory; year in a non-clinical subject, or in research or avel; and two years in a cardiac department: e programme should be elastic. There can be little dverse criticism of this, for it gives reasonable nphasis to a fundamental training in general edicine and a fundamental discipline in a laboratory ıbject. But it should be regarded as a guide to oung men and their advisers, not as a set curriculum.

The second term of reference was "conditions of ecognition as a consultant or specialist in cardiology." We find no mention of this topic in the report. Perhaps ome members of the committee thought that no onditions should be laid down, officially or unofficially, for such recognition. We could have wished hat all the members had held this view and had tated it. There may be room for doubt whether ualifications for holding the position of a physician r that of a surgeon in a national health service hould be officially defined; but it seems clear that o define the qualifications required of a cardiologist, nd to confine appointments to candidates satisfying he definition, would be to put cardiology in a straitacket. The administrative mind would argue that f centrally made regulations define a cardiologist, nd if a local-hospital board or management committee can appoint to a cardiological post none but man who fulfils the definition, then every hospital vill surely have a satisfactory cardiological service. With the incursion of the civil service into medicine, t would be all too easy for this kind of argument o prevail, and we must oppose it at every appearance In the example of cardiology the main fallacy is that prescribed training does not necessarily make a good ardiologist, nor the lack of it connote a bad one. The prescribed training takes no account of character and personality, which are important ingredients of the quality of any physician; it takes no account of development of the subject, which may outmode the prescription within ten years; and it leaves no door open for the odd original mind which may have found its own cardiological training during twenty years of practice in Burnley, or somehow equally unexpected. For undergraduate students a curriculum and a qualifying examination are necessary. For the major specialties they may perhaps be desirable But for the smaller specialties, which should be the growing changing pseudopodia of medicine, they will act as a fixative. Let hospital boards and management committees with their advisers be trusted to choose their own cardiologists, free from any central prescription. Responsibility not regulations will make them wise.

The third term of reference was "to make recommendations concerning the practice of cardiology in the hospitals and the National Health Service." The committee envisages at least one full-scale cardiac department in every region, associated with the central teaching hospital, staffed with physician, assistant physician, assistants, and residents, and disposing of its own 30–40 beds, outpatient section, X-ray and electrocardiographic equipment, and ancillary staff. The main function of this department is explicitly stated—namely, "advanced study of all problems connected with the heart and circulation." The department would not undertake to look after all cardiac cases attending the hospital to which it belongs, let alone all in the area it serves; and general physicians would continue to treat cardiovascular cases. Cardiology, in other words, makes no attempt to be a monopolistic specialty. The task of the pure cardiologist is to advance his subject and teach it to his less specialised colleagues. The flow of patients to his department must be carefully adjusted, to include difficult or problem cases for consultation, cases of the kind in which he may be specially interested, and a limited number of "routine" cases. The report says that the cardiologist in charge of this department "should be prepared to devote himself entirely to the problems of the heart and circulation, but he should have had a wide experience of general medicine." We may here ask whether the two years of general medicine, just after qualification, which are allowed in the prescribed training, afford a wide enough experience of general medicine to last a pure cardiologist through thirty professional years. In other words, is it wise to let a young man confine himself to cardiology from the fifth year of his qualified life onwards, and to staff central departments with men so trained?

For the cardiac department of a district hospital the report suggests that "a physician trained in cardiology" should be in charge. This suggests a better approach to specialism than the pure cardiologist's training It suggests a man who, for his quality and experience as a general physician, has earned staff status, and who in addition has had a cardiological training. He might be called the physician-cardiologist, and he would no doubt continue practising general medicine as well as cardiology in his district hospital. Among such men a few may show originality, or outstanding teaching ability, or some special achievement in cardiology that would mark them out as suitable heads of central cardiac departments. They should not be crowded out of that opportunity by the pressure of the "pure" strain of cardiological trainees. It would be better to limit the latter to a few, fill the lower appointments in the central departments largely, with general physicians adding cardiology to their training, and keep the top appointments widely open to those, from any quarter, who have shown their quality. The service, after all, needs few pure cardiologists, but many physician-cardiologists; the plan of training and the system of promotion should be designed mainly to develop the latter. The leaders, left to themselves, will come to the top as pure cardiologists. It would be a mistake to erect a promotion ladder for them; its lower rungs would become overcrowded, and it would shut out the original mind with the unusual training, whose potential contribution to the subject is great. Yet the report seems to picture that kind of ladder, without discussing its dangers. We doubt whether, in the words of the fourth term of reference, it would "pertain to the progress of cardiology as a branch of medicine."

HOPE GOSSE, Sir FRANCIS FRASER, M.D., Dr. GEOFFREY BOURNE, Dr. B. T. PARSONS SMITH, Dr. J. M. H CAMPBELL, Prof. J. CRIGHTON BRAMWELL, M.D., Dr. H. WALLACE JONES, Dr. D. EVAN BEDFORD, Dr. L. B. COLE, Dr. K. SHIRLEY SMITH (secretary), Dr. WILLIAM EVANS, Dr. C. W. C. BAIN, Dr. J W. BROWN, Dr. A. RAE GILCHRIST, and Dr. ROBERT MARSHALL.

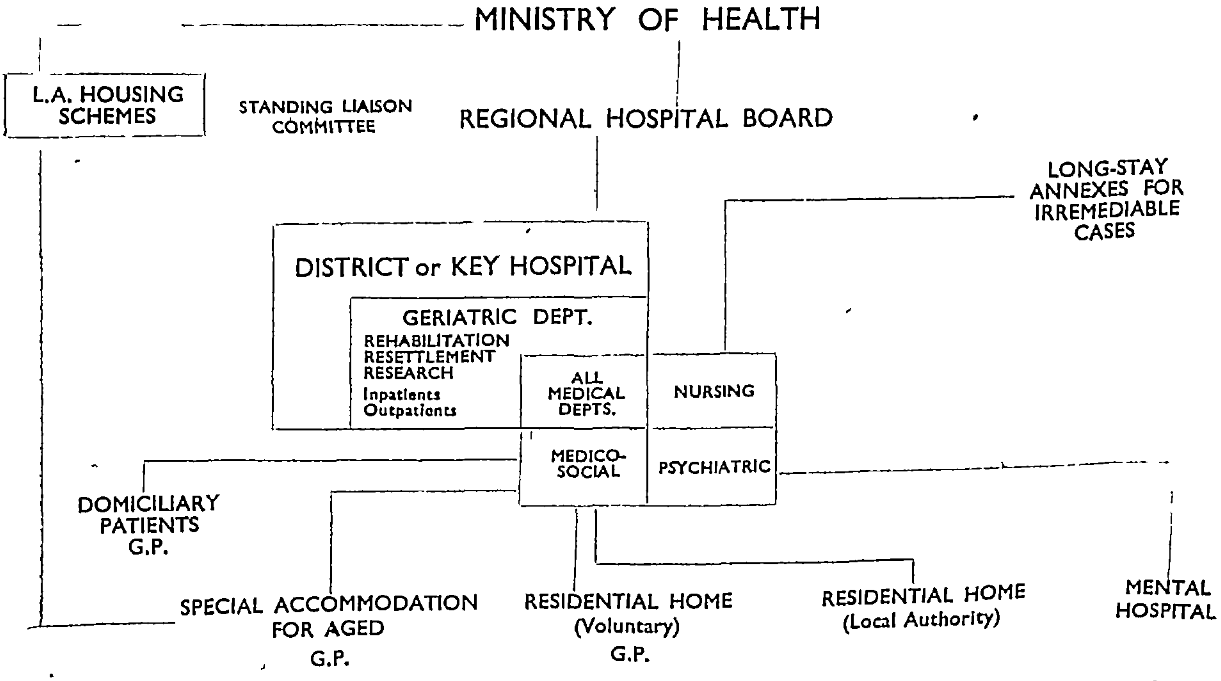
Care of the Aged

ENGLAND'S social services, like her industries, are now suffering as a result of their early start; for the system built up between eighty and a hundred years ago is in need of overhaul to meet the changed conditions. This applies with particular force to the care of the aged, whose number grows each year. Everyone is agreed on the necessity for action; but the question at this time of shortage in materials and in medical, nursing, and other personnel is not so much What ought we to do? as What can we do? A year ago the British Medical Association appointed a committee [1] to investigate the problem of our old people, and, though its report published this week [2] sets out to answer only the first question, the answer to the second is clearly implied.

The committee endorses the view, now gene supported, that the healthy old should be offe suitable dwelling-places in specially designed cott or blocks of flats; but the old, like the young, m wait their turn in the queue for houses, and report deals principally with the care of the and ailing. This, owing to acute pressure on hosp beds, is a question which calls not only for long-te planning but for short-term action. The committe plan (see diagram below) is based on geriatric unit selected general hospitals. These would be the h from which social and medical services would extended on the one hand to the old peoples' hon and residential homes and on the other to the lo term annexes. All cases of sickness, including th of mental illness, would, in the first place, be admitt for assessment to these units. The committe estimate is that of all new geriatric admissions, 40 would be discharged from hospital and 40% wou die, while 20% would need permanent nursi *attention in long-stay annexes. Existing* annex administered by the public-assistance authorities, very large; and the committee's recommendati that the units should be of not more than 30 beds c clearly not be effected for a decade or more W enlightened administration, however, nothing ne stand in the way of the further suggestions that t geriatric team "feeding" the annexe from the hosp should be responsible for the patients in it, and th grouped segregation should be adopted for the p manently incontinent and those with senile dement with individual segregation for those who are in pa or are dying, or whose condition might distress oth patients. This scheme of staffing would, by breathi new vitality into the medical organisation of t annexes, foster active treatment, thus reducing t stagnant pool of permanently bedridden and provid a larger outlet for the hospitals.

The report rightly stresses the importance of usi hospital beds to the fullest. It proposes that reside

A GERIATRIC SERVICE



---

[2] Report (1947) of the Committee on the Care and Treatment of the Elderly and Infirm. *Brit. med J.* June 21, supplement.

tial homes should be established for those considered fit for discharge from hospital. There is little doubt, as the article on Glasgow elsewhere in this issue suggests, that in such homes and in private dwellings systematic medical supervision, perhaps with out-patient attendance for physiotherapy, together with communal feeding and home-helps, would reduce the hospital admission-rate. Nowadays large houses are out of favour with the private owner; and the number of residential homes could be greatly increased without new- building, though not without costly adaptation. There are still insufficient home-helps for those who continue to live in their own houses. The experience of one area with an elaborate system of home-helps and district nurses is that their energies are being dissipated on long hours of work for hopeless cases living alone; and perhaps a temporary solution may lie in admitting without question to long-stay annexes and to residential homes only those requiring continuous supervision, while all others who have relatives would be returned to their care. This would release accommodation for the old people now struggling along alone and would enable home-helps to spread their services more usefully.

The idea of special geriatric units under the charge of specialist geriatricians has not commended itself to some, and not even to some geriatricians, who are reluctant to perpetuate the division of care of the aged from that of other patients. Medically, however, the division can perhaps be defended as reasonably as that of pædiatrics from the general body of medicine; and from the administrative angle a separate department is undoubtedly needed to supply the special services beyond the hospital for which the plan calls. It will be agreed, too, that the committee is right in seeing care of the aged, whether healthy or ailing, as a single problem, each aspect of which must be closely knit with others. Unhappily, the ground is to be shared by different authorities—the regional hospital board, the general practitioner, the local authority, and a new body to be set up to administer the poor-law.

> "The scheme may well fail unless, through the establishment of standing liaison committees, means are found to bring about such close coördination of the functions of the various authorities as will ensure the free passage of elderly people, under the expert guidance of the geriatric department, from home to hospital and from hospital to home in accordance with their changing needs."

This, so far as it goes, is admirable, but for the long-stay annexes it is not enough: these should surely be brought wholly under the control of the regional hospital boards.

Waste Not, Want Not

AT the beginning of the late war the Ministry of Health set up an organisation for the preparation and distribution of plasma for transfusion. During the war the organisation was expanded and achieved a very high level of efficiency. It succeeded in meeting virtually all the requirements of our civilian population and of the wounded evacuated to this country. Now, though the problem of the wounded is no longer with us, the demand for plasma is greater than ever before, and the resources of production are being strained.

In some respects the present big demand is justifiable. It is now widely realised, for instance, that when a patient is receiving his fluid intravenously it is necessary not only to meet his electrolytic requirements but also to ensure a sufficient intake of protein; accordingly it is customary to substitute a pint of plasma for a pint of glucose or saline solution during each twenty-four hours. Again, the unrivalled value of plasma in patients suffering from shock unassociated with hæmorrhage, as in severe burns, has been brought home forcibly to the younger generation of surgeons. Plasma-transfusion may be a life-saving measure in surgical or obstetric emergencies when compatible blood (or any blood at all) is unobtainable. It is essential needs such as these that the peace-time organisation for the supply of plasma is intended to meet. But there are undoubtedly many instances where this new-found weapon is being wielded unnecessarily. The surgeon about to engage on an operation a little beyond his proven powers very properly enlists every available means to promote success. The first thing that occurs to his mind is that hæmorrhage may be excessive, so an array of plasma bottles is assembled in the theatre and the first stage of the operation is to start an intravenous plasma infusion. Apart from the additional risk of homologous-serum jaundice that plasma carries, this is inexcusable waste. Very few operations need to be shored up by transfusions and then it is nearly always blood that is required. Another abuse of plasma is as a substitute for whole blood. It is indeed a very effective substitute in many conditions, but it can never be so satisfactory in cases of shock arising from blood loss, and its misuse in such cases is often simply the outcome of laziness. It is certainly more trouble to perform the preliminary tests necessary before blood is given, and blood may be harder to come by. But the choice of transfusion material should not be based on considerations of this kind. If the clinical indications are for whole-blood transfusion, plasma should be substituted only in the last resort. At present there is a wide variation in the proportion of plasma to blood required by hospitals for transfusion; in some regions the ratio is as low as 1 of plasma to 7 of blood, whereas in others it rises to 1 : 1—and this variation cannot be explained by lack of blood in certain regions. It must be that opinions differ on the indications for the two transfusion materials.

To facilitate the use of whole blood every modern hospital should have a resident transfusion officer attached to the pathological department, and also a central supply room. The transfusion officer will soon acquire the skill in immediate grouping and rapid administration of blood which only experience brings, so the mechanism for giving a blood-transfusion will run smoothly and readily. He will supervise the blood-bank maintained in his hospital by the regional transfusion centre of the National Blood Transfusion Service and ensure that the blood is wisely and economically used. He can also keep a panel of donors on whom he may call at short notice for special cases, and his ability to withdraw blood without causing pain or mishaps will encourage recruits. It is a pity that there is little inducement as yet for doctors to take up appointments as transfusion officers; the post should be filled by a fairly senior member of the hospital staff, preferably resident, and preferably possessing a knowledge of pathology, since compatibility tests should be done before all transfusions and only blood of the homologous group should be given An honorarium should certainly be attached to the appointments. The central supply room ensures that blood is readily accessible to the wards and theatres, and not, as is occasionally the case, tucked away in far corners of the pathological laboratory in the medical school. Further, the blood will be adequately preserved in refrigerators used only for this purpose.

A combination of efficient organisation on the part of the hospital authorities and intelligent application on the part of the doctor is essential if transf therapy is to function as a life-saving method precision. Plasma-transfusion is in danger degenerating into the "spot of" category— doctor who does a "spot of" surgery, who give "spot of" gas, or prescribes a "spot of" peni may well consider that a spot of plasma won't any harm. This attitude is both unworthy dangerous; plasma, like other foods and fuel, is short supply. It should be prescribed like chee on points.

Annotations

SULPHONAMIDES IN COMBINATION

ONE of the chief dangers of sulphonamide therapy has always lain in the tendency of these compounds to be deposited in the urinary tract and thus to cause blockage of the uriniferous tubules, the renal pelves, or the ureteral orifices. Sulphapyridine, sulphathiazole, sulphadiazine, and sulphamerazine are all liable to be thus deposited if the dosage is high or the fluid intake too low. 'Sulphamezathine' is more soluble and less dangerous; sulphanilamide never causes this trouble. The danger can be considerably reduced by making the urine alkaline, since these compounds and their derivatives are more soluble in alkaline urine than in acid—for example, the solubility of acetyl-sulphathiazole is only 7·3 mg. per 100 ml. at pH 6·4, but it is 31 mg. per 100 ml. at pH 7·6. The onset of urinary blockage is marked by one or more of the following signs or symptoms: pain in the loin (radiating to the groin) or abdomen, diminished output of urine proceeding to anuria, and macroscopic hæmaturia. The first step in treatment is to discontinue the sulphonamide. If some urine is still being excreted, fluids and alkalis are given to wash away the crystals; if blockage is complete, only enough fluid should be given to balance the loss through the bowel, skin, and respiratory tract,[1] and surgical measures should be urgently considered.

In the prevention of sulphonamide anuria reliance has hitherto been placed mostly on caution in giving large doses, on the administration of alkalis, and on the maintenance of a large fluid intake. A new approach has been evolved in Sweden by Frisk and his colleagues[2] on the principle that if two or more sulphonamide compounds are administered in combination the therapeutic actions of the different compounds are additive but their solubilities remain independent of each other. Accordingly it is possible to obtain a strong therapeutic action without the usual risk of urinary blockage. Apparently the same idea has been developed by Dr. David Lehr, of New York. Frisk et al. recommend a mixture containing 37% sulphathiazole, 37% sulphadiazine, and 26% sulphamerazine; this has been named 'Sulphadital.' In rabbits the greatest daily dose of the individual components which could be given without producing urinary concrements was only 0·4–0·6 g. per kg., whereas sulphadital could be safely given in doses of over 1 g. per kg. The maximum tolerated doses of the three components produced a blood concentration of about 3–7 mg. per 100 c.cm., whereas the maximum dose of sulphadital produced a blood concentration of 20 mg. per 100 c.cm. For the treatment of pneumonia the recommended course of sulphadital is two doses of 2 g. followed by repeated doses of 1 g., all at four-hour intervals. After fifteen hours the mean blood concentration per 100 c.cm. is 7·8 mg. free and 8·5 mg. total sulphonamide. If desired these doses can safely be doubled. Sulphadital has been used in Sweden in hundreds of cases of pneumonia and gonorrhœa with any signs of urinary blockage. Lehr seems to have a mixture of equal quantities of sulphathiazole sulphadiazine with similarly favourable results. simple scheme may prove a useful minor improve in sulphonamide therapy. But if a soluble but pow sulphonamide is all that is needed it is surprising t more attention has not been given to the British sulphamezathine, either alone or as a component these mixtures.

FROM SCHOOL TO WORK

> "Though it has been difficult to obtain precise informati it would seem that more than half the classrooms for chil of junior school age (7 to 11 or 12) are smaller than th stipulated by the Ministry."

Throughout the latest report[1] of the Central Advis Council for Education (England) to the Ministry of Edu tion the inadequacy of our present school buildings, b for juniors and seniors, runs like a sad refrain. They ag with the well-worn principle that good teachers are m important than good buildings, but point out that e the best teachers are handicapped by cramped and du schoolrooms, and by the lack of a school hall, or even larger "general activity" rooms required by the r building regulations of the Ministry. Poor quart make anything but "chalk and talk" methods teaching very difficult; and defective sanitary cloakroom accommodation make nonsense of the pri ples of hygiene and healthy living which the schoo supposed to teach. In the words of the National Fede tion of Women's Institutes, "so many schools are most depressing places—dull and dreary—if not actu unhealthy." In the circumstances, parents who send th children to private schools can hardly be arraigned snobbery: "when the conditions under which pu education is given are unwholesome," says the rep "parents who can afford it naturally seek an alternativ

The school medical service is also criticised, not the work it does but for its limited scope. The chil still examined only three times in his school life, as laid down in the Act of forty years ago. Special exami tions are commoner than they were, however, nea equalling the routine inspections in number, and more thorough. Treatment, made compulsory un the 1918 Act, has only been applied to defects of e and teeth, minor ailments, and chronic tonsillitis inflamed adenoids. The committee suggest that sup vision of health in schools should be comprehensive continuous, and should aim at fostering positive heal This means that the school doctor must have time consult with parents and teachers, to study the child in the classroom and at play, and to examine them m more fully, and if possible more often, than he does present. In the face of the shortage of doctors this hard to arrange. They suggest that for the mom the scope of the examinations should be impro rather than the number increased. The school nur they think, should combine her work with that of hea visiting in the children's homes. She should visit the school at least once a week and be responsible for routine semi-medical tasks which now fall to the teacher, such as eye-testing; she should also keep height and weight records of the children, as well as full records of her own work.

---

[1] School and Life. A first inquiry into the transition from sch to independent life. H M. Stationery Office. 1947. Pp. 1 2s. 6d.

The report is packed with sensible advice about the relationship of school and parents, the introduction of the young worker to industry, the effects of urban life on *children's standards, and the purposes of education.* Some examples of schools which have built up good relationships with parents make it clear that the teacher who is good at his job cannot settle down to a quiet evening once he has corrected the day's exercises. During term-time teaching is full-time work in a sense that would be accepted in few other occupations except medicine. But the teacher who gets to know the parents through parent-teacher associations, talks on educational purposes, and demonstrations by the children of music and singing, physical training, spoken English, and drama, and whose school becomes a social centre for the neighbourhood, is really interested in education, and is helping to rear young people with active minds and a grasp of social issues. This kind of work has been done too long under poor conditions. The report quotes Mr. Churchill's remark on the plans for the new House of Commons: "We shape our buildings and afterwards our buildings shape us." Children taught in many of our present schools are having no chance of developing fully.

"THE BIRTH OF A BABY"

In 1940 the National Baby Welfare Council introduced to this country an instructional film on pregnancy and childbirth.[1] A new generation has arisen since the film completed its tour in 1942; and it is once again to be released. Made in 1937 for the American Committee on Maternal Welfare, the film through the story of one woman's pregnancy and delivery gives a fair and fairly frank account of its subject. The first aim is plainly to encourage women to seek attention early in pregnancy; and the immediate effect of its earlier showing was increased attendance at antenatal clinics. The film also has wise words on related topics, such as abortion; and its honesty is calculated to dispel superstitious ignorance and to foster healthy curiosity in the process of childbearing.

Between 1940 and 1942 great difficulties were surmounted to secure a public showing of this production. The British Board of Film Censors, perhaps finding that it could not be placed in any of the three categories of approval (universal, adult, and horrific) withheld its licence. The board, contrary to popular belief, has no statutory powers or obligations; and local authorities, though usually accepting its decisions, are not bound by them. The National Baby Welfare Council therefore approached each of the local authorities in whose area the film was to be shown. There are some 1200 authorities in this country, and many, it seems, have no suitable mechanism for dealing with such applications. Sometimes they are referred to the watch committee, sometimes to the health committee, and occasionally even to the police-court. In the end few authorities withheld their permission; and, opinion having advanced in the last five years, it is anticipated that they will now be more ready to welcome the film. The L.C.C. has already granted it an "A" licence.

Nevertheless, the position is unsatisfactory. It may be hoped that this is the forerunner of other films on kindred topics. Is the road always to be so stony? Clearly, as with films for entertainment, local authorities should receive at least some guide from a qualified central authority; and perhaps the Board of Film Censors, reassured by the public's reception of this first film, may see its way to creating an educational category.

OLD WIVES AND GERMAN MEASLES

It has seemed odd that the old wives, always ready to find some appropriate explanation for congenital malformations, from being frightened by a dog to the more modern buzz-bombing, did not notice long ago the significance of german measles in early pregnancy. Dr. Hugh L'Etang's letter last week (p. 849) showed that in one case a mother did connect her german measles in pregnancy with her son's deaf-mutism, and sixty years before Gregg in Australia first suspected that the unusual number of cases of congenital cataract he was seeing in 1941 were the aftermath of the big epidemic of rubella which swept across the continent in 1939. But for that very exceptional epidemic the connexion might have remained unrecognised indefinitely, because in an ordinary epidemic year the number of cases of rubella in pregnant women would not be sufficient to produce an obvious rise in the incidence of congenital defects. The notifications in Manchester,[1] for instance, show that the epidemic of 1940 was remarkable for the relatively high incidence in women of child-bearing age, but if one calculates the probable number of women who were in the first three months of pregnancy at the time of their rubella—as can be done by applying the Registrar-General's maternity incidences—it is clear that only 20 or so fœtuses in Manchester were in danger from that epidemic, compared with about 14 in 1944 and less than 10 in any other year since 1940. Moreover, we do not yet know how many of these would escape damage altogether, or how many would be so severely damaged that they would be aborted or born dead. It might be practicable to obtain this information by following up the married women in the Manchester notifications (as was done in Milwaukee), but in the meantime anyone who encounters a case of miscarriage, stillbirth, or normal birth after the mother has had an exanthem early in pregnancy should report it, either in a medical journal or to the research-workers now investigating the subject for the Medical Research Council. And whenever a child is born with a congenital defect a close inquiry should be made into the events of the first few months of the mother's pregnancy.

TREATMENT OF PENICILLIN URTICARIA

Pretty well any remedy, whether organic or inorganic, may produce sensitisation; and the fact that penicillin occasionally does so is neither astonishing nor disappointing. Moreover, the observations of Dr. Steingold in this issue suggest that at any rate some of the sensitisation reactions are the effect of impurities rather than of penicillin itself. Though skin-tests are not a wholly reliable index of susceptibility to a drug it was a striking finding that in his 4 cases of penicillin urticaria the patients all gave positive reactions to two commercial brands of penicillin containing 1420 and 450 units per mg. but negative reactions to a "pure" preparation containing 1666 units per mg. It is conceivable that the patients were not sensitive to all forms of penicillin, and that the penicillin in the pure preparation was in a form to which they were insensitive; but sensitivity to impurities in the commercial preparations is a far more likely explanation.

The incidence of urticaria during penicillin therapy varies considerably, as would be expected if it is largely the result of impurities. Dawson and Hobby[2] saw 3 examples in 100 patients; Pillsbury et al.[3] saw 2 in their first 200 cases of syphilis treated with penicillin but 12 in the next 200. Reactions are more common during second or subsequent courses of penicillin than during the first course, though 3 of Steingold's 4 patients developed urticaria in their first course. A reaction in one course does not necessarily indicate that the patient will get one in a subsequent course—again this is easy to understand if impurities are the cause. Skin-tests cannot be relied on to predict whether or not a patient will react to the drug. As usual with drug reactions there is an incubation period, rarely shorter than five days but sometimes much longer, between the start of penicillin therapy and the appearance of urticaria; in Steingold's cases the rash appeared on the seventh or eighth day of treatment.

---

[1] Clayton-Jones, E. *Lancet,* Jan. 11, p. 56.
[2] Dawson, M. H., Hobby, G. L. *J. Amer. med. Ass.* 1944, 124, 611.
[3] Pillsbury, D. M., Steiger, H. P., Gibson, T. E. *Ibid,* 1947, 133, 1255.

The antihistamine drugs work very well in penicillin urticaria. A dose of 50–100 mg. of 'Benadryl' or 'Pyribenzamine' three times a day will usually give relief in twelve hours, but it must be continued for as long as the rash would last without treatment or the urticaria will reappear. If the reaction is severe benadryl can be given slowly intravenously in a dosage of 5–10 mg. in 20 c.cm. of isotonic saline, but this is still rather an experimental procedure. Pillsbury et al. mention the "decidedly startling" hypnotic effect of intravenous administration and are not convinced that it is always safe; adrenaline seems to be as effective and its action is more predictable. As a rule they stop the penicillin immediately when a reaction appears and give benadryl or pyribenzamine 50–100 mg. t.d.s. or four-hourly by mouth. If the reaction subsides they give a test dose of 1000 units of a different brand of penicillin, having adrenaline at hand in case of emergency and continuing with the antihistamine drug by mouth. If there is no reaction to the test dose in six hours they give another 10,000–20,000 units, and if this is well tolerated they then return to the full dosage. The benadryl or pyribenzamine may be reduced gradually and can sometimes be given up after two or three days.

Drug reactions of this kind might have been said to have lost their terrors but for one snag—that in a few people the antihistamine drugs produce sensations so unpleasant as to prohibit their use.

HOW TO POISON RATS

It is obviously futile to poison bait with a substance whose taste is unacceptable to rats; but the discovery of a poison whose taste does not offend is not the entire solution of the problem of destroying these pests. Contrary to general belief, rats are not clever at discriminating between poisoned and harmless bait; they owe their multitudinous escapes almost entirely to their timidity. When bait is freshly laid on their runs, rats will at first give it a wide berth, even when it is not poisonous. Several days may pass before they investigate it, and even then they nibble only a very small amount. In this way, if the bait is poisoned, sublethal doses are ingested, and the discomfort that these cause only makes the rats bait-shy.[1] Sublethal doses sometimes even produce tolerance, as in the case of α-naphthyl-thiourea, known to the trade as 'Antu.'[2]

If either shyness or tolerance results from laying a certain poison, it is better to try again, using fresh bait with a different poison. But it is still better and far more humane to prevent the development of shyness and tolerance. This is done by prebaiting: that is, by laying easily edible quantities of harmless bait in the same places for several consecutive days until the rats, suspicious of anything new, become familiar with it and eat without fear. Then by poisoning all the bait on a single occasion a kill of 85–100% of the local rat population can be confidently expected. Mass extermination is the only way to get rid of rats. Their net reproduction-rate is so high that killing a few rats occasionally is mere waste of time.

The choice of poison is important from the view both of efficiency and of humaneness. Zinc phide is now generally preferred, as being highly e and less inhumane than most. Red squill is of u quality, often ineffective, and extremely inh For brown rats antu is highly toxic, with a LD 4 mg./kg., and appears to cause relatively little For the black rat, however, which is the usual of the plague flea, its LD_{50} is much higher—n 250 mg./kg., as compared with the 40 mg./kg. of phosphide and 190 mg./kg. of arsenic.

MEDICAL HONOURS

Among the honours to medical men in the B Honours list those awarded for services to the this year take precedence. Sir Godfrey Huggins, minister of Southern Rhodesia since 1934, beco privy councillor, and Surgeon Vice-Admiral H. St. Colson, director-general of the Navy, a knight com of the Bath. In the Royal Victorian order, w reserved for personal services to the Royal House Hugh Lett, honorary secretary to King Ed Hospital Fund, is appointed knight commander, Surgeon Rear-Admiral H. E. Y. White, who accomp the King on his tour to South Africa and has his honorary surgeon since 1936, was promoted t same rank. Dr. Alexander McCall, the Foreign tary's medical attendant, and Dr. T. W. Meagh former lord mayor of Perth, Western Australia, become knights. Knighthoods have also been conf on Dr. W. Norwood East for his services to the of criminal psychology; on Prof. D. K. Henderson, holds the oldest chair of psychiatry in the country, in the University of Edinburgh, and has done muc further the development of psychiatry in relation t State; on Prof. E. L. Kennaway, F.R.S., lately dir of the Chester Beatty Research Institution of the Cancer Hospital, who laid the foundations of the stu experimental carcinogenesis; on Mr. A. H. McIndoe, sultant in plastic surgery to the Royal Air Force, whose on behalf of the few will be remembered by the many Dr. R. A. Young, consulting physician to the Midd and Brompton Hospitals, who has for many years ex a soberly progressive influence on the treatmen tuberculosis; and on Colonel G. R. McRobert, l professor of medicine at Madras. To these and al other colleagues whose honours are listed on an page we offer congratulations.

INTERNATIONAL CONFERENCE OF PHYSICI

The preliminary programme has now been publi of the international conference which the Royal Co of Physicians is holding in London from Sept. 8 t under the presidency of Lord Moran. The work o conference has been divided between the follo sections: cardiology (chairman, Sir Maurice Cass disorders of the chest (Sir Robert Young), dermato (Sir Archibald Gray), neurology (Dr. Gordon Hol F.R.S.), pædiatrics (Sir Leonard Parsons), psychi (Dr. Bernard Hart), social medicine (Sir Wilson James and general medicine (Lord Moran). The speakers include visitors from America, Belgium, Czechoslov Denmark, France, Holland, Norway, Sweden, Switzerland, and the full programme will be foun our advertisement columns. Dr. G. B. Mitchell-H is the organising secretary of the conference, and doc who wish to attend should apply to him for ticket admission at the college, Pall Mall East, S.W.1.

Dr. **Leonard Findlay**, consulting physician to Queen Elizabeth Hospital for Children, London, formerly professor of pædiatrics in the University Glasgow, died at his home in Farnham on June 11. He was 69 years of age.

Modern Care of Old People

IV

A CITY'S PROBLEMS

GLASGOW, the largest municipality in Britain, with a population of over 1,000,000, has 120,000 old-age pensioners. The centre of an industrial area, it has special problems, for the poorer people in such an area are said to age more rapidly than those elsewhere. Not so long ago it was a depressed area, and unless light industries are established before the end of the boom in steel and shipping it may become one again. In 1939—the latest year for which returns are complete—the rate of poor relief per 10,000 population was 850, compared with just over 200 for London and just under 200 for Birmingham. Finally, with its heritage of slums and overcrowding—60% of the population live in one- or two-roomed dwellings—Glasgow must balance the claims of the aged against the equally just demands of the young. Against this daunting background the welfare and public-health departments, and the university authorities largely inspired by the late Prof. Noah Morris, have set about improving the lot of the old people, and studying their needs. Professor Morris recently held one successful weekend course in geriatrics for doctors, and hoped to arrange others.

WELFARE DEPARTMENT

The aged include the well and fit, who are capable of living alone or with their family; the ill, feeble, or infirm; and the ailing, who are able to look after themselves with a little help. The first group simply need suitable housing. At present some elderly people are living in houses with 3–5 rooms, now too large for them but suitable for those with large families who are confined to small tenement-dwellings. The plan is to help both by decanting the old wine into newer (and smaller) bottles. The housing committee of the corporation have had designed a group of 25 cottages for ageing couples, and a site has been earmarked. New housing estates will carry a proportion of houses specially suitable for the old. Progress thus will be slow. Sometimes help can be given in finding a suitable small house; but these are scarce, and their owners more often than not insist on selling outright. Other ways, therefore, must be found. Glasgow's experience of hostels for the elderly, run by caretakers, has not been entirely happy: communal bathrooms, lavatories, and kitchens have been found to foster communal strife, and the authorities have turned their faces against extension of this scheme. Instead, they have decided to take over large houses and convert them into separate small dwellings. This is known to be a temporary and unsatisfactory expedient, since most rooms in these houses, being very large, with high ceilings and only one window, are difficult and expensive to divide and convert.

CROOKSTON COTTAGE HOMES

There is no hint of expediency, however, about the cottage homes constructed at Crookston, five miles outside Glasgow, just before the war. Here the welfare department decided to set up, near a home for the infirm, a village for the aged who are still fit enough to keep house. The plan was for 64 flats for couples and 144 for single people; but building was interrupted by the war, and only half that number was completed.

Though in open country, the village is within a penny bus-ride of shops. Surrounded by grass, the two-story buildings are faced with distempered roughcast, and have roofs of variously coloured tiles. They are constructed in pairs at right-angles, with a common dayroom at the angle. The ground-floor flats each have a front porch, while those on the first floor have a balcony. The occupants reach their dayrooms by way of a covered corridor.

The front door leads directly into the living-room, from which the bathroom and kitchen open. Opposite the fireplace is a bed-recess. Every living-room has a pull-out table which will seat four, 2 easy chairs, 2 straight-backed chairs, and an inset bookcase and cupboard. A wireless speaker (supplied from a centrally controlled set) can be turned on at will, and there is an electric point for iron, lamp, or personal radio-set, as well as an electric clock. The room is heated by a coal fire, above which is a small oven, suitable for keeping food hot or for drying sticks; and ample coal is delivered to the door three times a week.

In the bed-recess the light is set at the head of the bed; there are a large wardrobe-cupboard, two chairs, and a built-in dressing-table incorporating an electrical convector (air heater). The floor, like that of the living-room, is covered with linoleum and a rug, and the walls are light cream. The rooms are thus light and cheerful.

Beyond the living-room a small corridor leads to the backdoor. On one side the kitchenette contains a small electric breakfast cooker, ample cupboards and drawers, a storage cupboard with outside ventilator, and large drainage boards on each side of the sink. There is enough cutlery and china for the entertainment of visitors.

The bathroom-lavatory on the other side of the corridor contains a sitz bath (water is heated centrally), and a clothes horse for those who wish to do their own washing. Normally all laundry is done for the occupants, being collected on Thursdays and returned on Saturdays. Linen and, if necessary, clothes are provided; uniform clothes are of course carefully avoided.

All the rations are handed over each week to the occupants, except 1 oz. sugar and the meat ration. These are retained for the midday meals, which must be taken in the dayrooms, the aim being to ensure that at least one good meal is eaten each day.

The dayrooms are large and airy, and contain two electric fires—one in each of the alcoves—upholstered seats along the sides, tables for 6–8, an electric clock, and radio. Leading off each of them is a small servery, with an electric cooker, to which the food is sent for distribution from a central kitchen. Strangely, it may seem, the old people do not resent this enforced communal feeding; but they strongly resisted the suggestion that the dayroom meals should be abandoned in favour of a united meeting in the large assembly hall, now released by evacuees. A communal spirit has grown up among the cottagers, who meet in their dayrooms each evening in the winter to talk, or play cards or dominoes. Sometimes competitions are arranged, and in summer the bowling-green is the centre of social life.

Domestic help is given in the distribution of meals and the washing-up of dishes after the midday meal; but the cottagers voluntarily help in this work. Help is also available to those who find that housekeeping is getting a bit beyond them. No extra furniture is necessary, but cottagers are encouraged to make the cottages homely by bringing with them their own particular chattels. All like to adorn their windows with plants and flowers; but, perhaps because nearly all have been tenement-dwellers, there has been no demand for personal gardens.

If a cottager is off colour, she is visited by a nursing sister; if she proves to be really ill, she is removed to hospital, but if she simply needs some extra attention she enters the nearby home. Her cottage, if she was living alone, is retained for her, at least for a time. Those with failing health are admitted to the home; and since this is felt to be a step towards the end, the matron, who is responsible for both cottages and home, tries to leave it to the cottagers to judge for themselves when their housekeeping days are over. Since the home is near the cottages, admission does not mean the end of social life; the other cottagers constantly visit their friends in the home.

How has this scheme worked? Judging by the spontaneous praise of the cottagers, brilliantly. They appreciate the good houses and their freedom; they can come and go when they will, and are subject to no rule, except that they shall not be a nuisance to their neighbours. "The only suggestion I've got," said one old lady, "is that people should have these houses when they are younger."

Visits are encouraged, for the one dread in the minds of most is that they might be forgotten. The friends and relations, in turn, welcome the chance of a trip into the open country. So far no crafts have been developed in the village, but relatives often help with a little extra money; otherwise everything is found, and 2*s.* a week pocket-money is provided.

Cottages at Crookston.

The cost of the buildings, before the war, was £450 for a couple's house, and £345 for a single person's house; the furniture cost an additional £50 or so. The present-day overall cost to the local authority of each tenant is 51*s.* 11*d.* per week, including upkeep of the house, food, clothes, and pocket-money.

In Glasgow, as elsewhere, the authorities are indignant that these old people are denied their old-age pension. Under the Old Age Pension Act of 1906 anyone entering a rate-aided institution for maintenance only lost the right to his pension. This was perhaps reasonable enough when pensions were non-contributory and when there was a poor-rate. Now pensions are contributory and a block grant has supplanted the poor-rate. Repeated attempts to get the anomaly corrected have failed. Some encouragement to other authorities to follow Glasgow's lead might be provided by transferring the amount of the withheld pensions to the responsible authorities. It would, however, be better still—and a great deal more just—if the pensions were paid to the old people, who could then pay rent and feel that they were contributing to their own upkeep rather than relying on municipal charity. This anachronism extends at the moment even to hostels for old people. If these were controlled by the housing department, pensions would be payable; but since the housing department has no authority to provide care as well as shelter, hostels must be managed by the welfare department.

HOSPITALS AND HOSPITAL ANNEXES

In Glasgow, as elsewhere, more hospital beds for the aged, and particularly for female medical and psychiatric cases, are badly needed. Here, as in other centres, the load falls principally on the municipal hospitals. At Stobhill Hospital the elderly are deliberately not segregated from other patients during investigation, nor are they immediately divided into acute and chronic cases. The belief, now often expressed, that geriatric units should be established in acute hospitals is resisted on the score that treatment of the aged, though it may be open to special research, is not in itself a specialty but belongs to the general body of internal medicine. The estab ment of geriatric units, it is held, would only div still further the treatment of the aged from ger medicine. This divorce is so complete in many teac hospitals that most consulting physicians have experience, and thus no interest, in the problem ageing; while students who later, in practice, r remedy the ills of the aged are never trained for task.

The hope of many in Glasgow is that units for long-term sick will be established as part of, and st from, the acute general hospitals. Patients would transferred to these long-term units only after prelimi investigation in the acute general wards. This w ensure continuity of treatment, and also impress m and junior doctors with the importance of such u they would thus become more ready to serve in t

In Glasgow, as in many other centres, long-t patients are accommodated in institutions under welfare department. These institutions admit a "casuals," also receiving a number of non-sick eld people who require accommodation; and there is a reasonable case for retaining them under the wel department. At the same time, if, under the new the welfare institutions (which at the present time not designated as hospitals) remain under the l authorities while the hospitals, as is certain, pass of local control, close liaison will be almost imposs The solution may lie in transferring the "casuals," w these are greatly outnumbered by the ailing, to o institutions, and placing the existing institutions wh under hospital control.

Staffing of these institutions is nowhere easy. I large Glasgow institution a plentiful supply of l and efficient nurses has been obtained by recrui ex-Servicemen with previous nursing experience, but supply of female nurses still remains difficult. Equ the supply of Queen's nurses, who undertake as of their general nursing duties the care of a good num of elderly chronic sick at home, is also limited; recruitment to the service is diminishing at present. the other hand, Glasgow public-health department established a most successful scheme of home he Over 400 are employed, three-quarters of them dea with cases of general sickness, a large number of w are of the elderly infirm group; the remaining qua is allocated to maternity cases. It is already evi that this organisation is saving hospital beds by provi assistance to relatives. In addition, the helps l proved most useful in looking after elderly persons li entirely alone. So far the services of the helps h had to be limited to a certain period of time, experience is showing the scheme to be adaptable future needs, and it is hoped that it will become integral part of the organisation for the care of chronic sick.

FUTURE PLANS

The present aim is to link more closely the hosp with the long-term unit on the one hand, and with home and hostel on the other. Glasgow hospitals wo in particular, welcome any improvement in the "mod lodging-houses, since many of the patients readmit from these places—for example those with chro chest conditions—would not need to return to hosp so soon or so often if they had a little more care a attention outside. Perhaps the answer lies in hos controlled not by caretakers but by wardens. W the hospitals pass outside local control institutions int mediate between the hostel and the hospital may be up. The purpose behind all planning is to keep old peo on their feet for as long as possible and to enable th to remain independent.

One proposal is that clubs should be set up, alo the lines of the Peckham experiment. To their memb e clubs would afford a means of occupation and munity of interest; while for research-workers they ld provide unparalleled opportunity for studying scence. They could, moreover, fulfil other useful rposes: members could be trained in profitable fts; social services could be extended to members' mes; and the clubs could act as links between hospital d home. It is thought, too, that the provision of ysiotherapy might help to reduce the call on hospitals, essential condition of membership would be periodic ysical overhaul; and though older people might not ke to it as readily as the younger, it is anticipated at, once the ice was broken, this would not deter many m participating. Since the clubs would have to be se to members' homes, many would be needed to ver such a large city as Glasgow. It may be hoped, wever, that this objection will not prevent the establishnt of at least one or two pilot units.

HOSPITAL RECORDS

A Plea for Reform

H. Cotton
F.S.S.
RECORDS OFFICER, NUFFIELD BUREAU OF HEALTH AND SICKNESS RECORDS, OXFORD

During the next few years there will be much dis-ssion about the form and nature of records to be kept y hospitals, health centres, school medical departments, nd practitioners in all arms of the National Health ervice. It is believed that in the new service hospital orbidity statistics will be collected on a national ale, with provision for central, or at first regional, nalysis. Many hospitals, aware of this possibility, re overhauling their records systems.

Inspection of the systems used in a number of large oluntary hospitals reveals a serious situation. The ct is that records, in most of our great institutions, ave not occupied their rightful position. This is no ere question of filing and indexing; the root of the rouble is deeper. If it be true (as medical students are ontinually being reminded) that a patient is not simply brain, a stomach, a complex of nerves, an assembly of ssues, but a whole individual, then it is a fundamental istake to record his medical history in a series of nconnected notes. As specialisation in medicine grows, nd as the unity and continuity of medical care is estroyed, so there is increasing need to integrate the ndings of each separate specialist and to reconstitute, n paper at least, the whole individual. In so far as he unit is not the whole individual, but rather some natomical fraction of him or some episode in his life, he human concept recedes and the record becomes a andful of jottings about a sick heart, a sick bladder, r a sick brain.

Some hospitals keep separately their records of npatients and outpatients, who are often the same people; nd the link between the two records is often tenuous. thers keep separately the records of patients dealt with y different wards and clinics. One of the largest ospitals in the country is at present considering a roposal that each medical and surgical "firm" shall naintain its own clinical record system. Many hospitals ave no department which can be described as the ecords department; records are sometimes a sideline f almoners, sometimes a sideline of stewards. Rarely re records regarded as worthy of specialisation. Several ndependent *staffs* may operate the records system—or example, outpatients may be registered in one place nd their records filed in another, while inpatient records re stored several blocks away. Sometimes members of these unconnected staffs are unaware of what happens to records outside their own offices. Never is this lack of coordination more apparent than when a record goes astray. Requests for a missing record travel from one person to another, with much fruitless searching, and finally no-one is really to blame. Even if the missing record should turn up among the magazines in the housemen's common-room, the person requiring it is so thankful to get it that he rarely institutes measures to prevent a repetition.

FILING THE NOTES

Again, in some hospitals records are held of so little account that their accessibility is not regarded as important. Often they disappear into the maw of a primitive filing system. Sometimes one finds that inpatient records are bound in volumes, each volume containing perhaps 100 notes of cases seen by a particular physician or surgeon. Within the covers of the volume the notes may be arranged in chronological order or they may not. When an old note is wanted, it is necessary to know a number of details, including the name of the physician or surgeon (who may have been dead for years), the date of the patient's admission, and the number of the note in the volume. The patient's name and present address, together with a vague notion of the year in which the patient last came to hospital, may be all the information one possesses. It becomes necessary to consult more indices and musty old registers in order to find a clue which will lead to the right volume. On finally emerging triumphantly with the book, one is condemned to carry round with the prize 99 unwanted notes. I have seen 20 bound volumes, containing 2000 notes, on the desk of a surgeon who wished to look through 70 cases of a particular disorder. The 1930 notes he did not need sat in front of him for several days; anyone else wanting to see any of them would have had to wait his turn.

Also it is too much to expect good notes to be made if the writer knows that they will be read by the patient. In some of our most famous hospitals the patient is handed his own notes, and naturally he whiles away the waiting time by reading them. He may even transcribe them and take the copy to be solved like a crossword puzzle with the aid of a dictionary. (Indeed I know of a case in which a note was returned by the local cleansing department, having been retrieved from the dustbin into which the baffled patient had hurled it.) When a patient is attending more than one department of a hospital and has separate notes for each—all of which he can read if he likes—he is apt to form a low opinion of an organisation which cannot build its several bricks into a respectable wall.

Organisation is not the only trouble. If the medical staff do not regard notes as valuable documents there is no incentive for the administration to plan their proper care. Notes belong to the hospital and should not be kept at private consulting-rooms for long periods. On the other hand, the hospitals should provide proper secretarial help so that visiting staffs can dictate notes before they leave the hospital; for if this is not done the doctors can hardly be blamed for pocketing the notes and dictating additions to their own secretaries at some convenient time.

To continue the catalogue of defects would be tedious. Enough has been said to show that a revised record-keeping system should be based on the patient as the unit, and that however many hospital admissions he may have had, however many different departments he may have visited, and however long the intervals, *all* the information should be kept together in ordered fashion, so that the record shall provide a complete account of *his whole hospital* experience. This account, as we have seen, can only be complete and uninhibited if its circulation is restricted to those responsible for the patient's care.

SUGGESTED SYSTEM

"Merely to collect in a single folder all the data on one patient does not accomplish the purpose of a unit record"[1]: the material must be so arranged that any particular kind of note is identifiable among the others, and the general outline of the history immediately apparent. With a record which covers numerous admissions and numerous outpatient attendances, this is far from simple. The choice lies between (1) a strictly chronological arrangement of the material, and (2) the grouping of all the notes of one type—e.g., pathological reports, radiological reports, and operation notes. This assembly of all the special reports of a single kind is tempting in that it makes it easy to follow progress in that particular line, but the temptation should be resisted. A front sheet which details the several admissions and periods of outpatient attendance, and the diagnoses, followed by a chronological record consisting of progress notes interspersed with special reports, provides the most practicable answer. This mixture need not be confusing if each of the component forms has a distinctive mark, enabling it to be recognised at a glance, and if each has its own place in the notes. A parti-coloured mass of papers is not desirable; all records should be made on white paper, and these can be distinguished by tabs "staggered" down the margin, or by coloured signals printed in a corner.

TABLE I—CASES OF GASTRIC DISORDER DISMISSED FROM HOSPITALS IN OXFORD AREA DURING 1945

—	Males		Females		Sex-ratio M/F
		%		%	
Gastric ulcer ..	22	3·6	9	2·1	2·4
Duodenal ulcer..	52	8·5	5	1 2	10 4
Other gastric disorders ..	535	87 9	415	96·7	1·3
Total ..	609	100·0	429	100 0	1·4

Elaborate pro-formas should not be indulged in too freely, since these tend to formalise note-taking, and, as many good judges think, encourage staffs to rely upon printed headings at the expense of narrative. The indispensable headings appear to be those for identification data, personal and family history, account of present complaint; physical examination, provisional diagnosis, and progress notes. Radiological, operation, anæsthesia, electrocardiographic, and other special reports, diet and prescription sheets, photographs, temperature charts, authorisations of various kinds, and correspondence will complete the normal record.

From a note thus assembled the registrar should prepare a summary, of which a copy should be furnished to the patient's private doctor. Lastly, from the notes and summary, a coded "transcription" should be made of the basic demographic and clinical data, to be used in a card-recording system. This may work on ordinary index cards, on hand-sorted punch-cards (holes round the edge, needled out on demand), on rod-sorted punch-cards (slotted cards, hand-operated sorting in a selector-box), or machine-sorted cards (machine-punching, electrical, or mechanical sorting and tabulating).

COLLECTING THE DATA

The transcription of much clinical data—for example, in a detailed survey of a particular disease—should be made by someone medically qualified. For pictures of the case-load and case-mortality, diagnostic frequencies, and age and sex distribution, transcription by lay workers, if they are properly trained, is usually satisfactory.

From good basic records card-systems can be up which will save the clinician hours of laborious Lately an obstetrician told me that he had set his to sort out from 10,000 case-notes all the cases of p prævia; every note had to be scrutinised. When the wanted notes would then be further examined several variables, after which correlations would attempted. Even if 200 notes an hour were (an unlikely average) this meant 50 medical man- on the first search. Had the notes been tran pari passu as suggested above, and cards punched machine-sorting, the wanted cases could have isolated in half an hour. The selected variables then have been tabulated for correlation in a few ho and the notes themselves "pulled" for more de inspection, if necessary.

The value of hospital records for clinical r needs no emphasis; but, as this is a plea for record-making, a straightforward example (with pretension to originality) may be conveniently ind here. Table I refers to 1038 cases of gastric dis "dismissed" from (i.e., discharged from or dying hospitals in the Oxford area during 1945. The m cards were extracted from a pack of 16,655 cards diagnoses) in $1^1/_2$ hours.

The table shows that for every 10 diagnoses of g disorder in women there were 14 in men. For e woman diagnosed as duodenal ulcer there were 10 4 and for gastric ulcer there were 2·4 men for every wo Every 12th man in the whole group had a duod ulcer, but only every 85th woman. These figures in further inquiry. The absolute numbers are small, true, and the argument for uniform records is strengthe by this fact. Bigger numbers are needed if solid infere are to be drawn. What is the national experience, how do regions compare in the matter of the ulcer ratio, for instance? What is the occupational distr tion? There are plenty of guesses, but no figures. as in this one simple instance, so it is in many n difficult problems: the mortality-rate from appendi is known but not the morbidity-rate; the cancer de rate per 1000 population but not the cancer incide rate; the number who succumb to rheumatic he disease every year but not the number who suffer live on in a state of permanent cardiac impairm These and many other questions can be investiga along with questions of symptom-frequency in ce diseases, treatment responses, operation results, an thetic reactions, and the like.

TABLE II—OXFORD AREA PATIENTS DISMISSED IN 19 SELECTED DIAGNOSIS GROUPS BY PAY-STATUS AND AVER DAYS' CARE *

discharged from New York hospitals in 1933 a question was raised which, if it could be answered, would be highly relevant in Britain today. "To what extent do factors other than diagnosis influence length of hospital stay—that is, what reasons may cause patients with the same diagnosis to require hospital treatment of different duration?" There is an obvious relation between age of patient and length of stay, and there is also a finance relation. A table published in the New York study showed that "pay" patients (full or part pay) had a shorter overall average stay than "non-pay" patients. "Pay" patients stayed an average of 11 days each, "free" patients 16 days each, and "public charge" patients 21 days each. A survey of 60,743 Ontario patients in 1938 revealed that patients paid for by government and municipal authorities stayed longer than "paying" and "private" patients. According to the report[3] "average durations of care by sex, age, and diagnosis show uniformly that the duration of hospital care among those whose maintenance is paid for by the State is consistently and substantially higher than for patients who contribute to the cost of their maintenance." What is the British experience? The records which could have furnished it have not been kept. The Oxford area experience for 1946 is given in table II.

Because of the numerous patients in the "pay-status unknown" category, it is not possible to say whether non-paying patients stay consistently longer than paying patients, but in three of the four groups of disorders they appear to stay a little longer. The high average stay of paying patients with circulatory disorders is caused by a small number of chronics in local-authority hospitals.

The Oxford figures by themselves cannot be taken as representative of British experience. To a country which is about to convert all its inhabitants into non-paying patients, an extension of table II to national dimensions would be valuable. (This table, necessitating the sorting, counting, and tabulating of 6968 machine cards by diagnosis, pay status, and days of care, was prepared in $4^1/_2$ hours.)

There is a third direction in which hospital statistics can be helpful—i.e., in throwing light on the problems of everyday life. "Keep Death Off The Roads" is a commendable slogan, but tables III and IV suggest that "Keep Injury Out Of The Home" is equally desirable. These tables were produced from machine-card tabulations in less than one day.

THE THREE ESSENTIALS

I realise that the clinician's attitude towards a drive for better documentation and better statistics in hospitals may be, in part at least, defensive. Already having crowded wards, heavy outpatient duties, and much paper-work, he will give but a faint welcome to ideas for improved notes and scientifically designed transcriptions. Some, indeed, harbour a definite prejudice against the routine tabulation of data; doctors are not the only people who have a deeply rooted suspicion of statistics. But few will dispute the merits of the unit medical record system, and none, one may hope, will object to the rationalisation of record-*keeping* as distinct from record-*making;* the introduction of time-saving techniques for registering and filing records and producing them on demand; the employment of such commonplace aids to efficiency as folders and stationery of uniform size, designed for simplicity and speed in use; and the maintenance of diagnostic indices. To what, then, would hospital clinicians commit themselves if they consented to the modernisation of their hospital records? Only these three conditions are essential:

1. Consultants would require all members of their firms or units to maintain a high standard of note-taking and would personally "audit" notes on occasion; registrars would conscientiously summarise notes and supervise the note-taking of housemen; juniors would make it a matter of pride to take adequate, lucid, legible notes routinely, realising that by so doing they would be preserving factual data of cumulative value. Department heads would recognise that their contributions should fit in with the master records-plan.
2. All would recognise that record-*keeping* and analysis are specialised activities, involving complicated techniques for those immediately responsible, and comparable in this sense with those of the pharmacist, the almoner, and other medical auxiliaries. These activities necessitate the employment of a trained hospital records officer with a proper allocation of staff, space, and equipment.
3. Some hospital clinicians would serve on a records committee, meeting regularly for an operational check-up and to pass judgment on new ideas, all of which would be submitted to the committee before being put into action.

AMERICAN DERMATOLOGY

FROM A CORRESPONDENT

IN opening the 67th annual meeting of the American Dermatological Association, held at Murray Bay, Canada, on June 2–5, Dr. PAUL A. O'LEARY, the president, discussed the American methods of training dermatologists, and said that in the United States more ex-Service doctors had applied for postgraduate instruction in dermatology than for instruction in any other branch of medicine. His address was followed by 24 papers, each discussed at some length by several of the 84 members who attended. All these communications will doubtless be published in due course, but shortage of paper is retarding the speed of publication in the States, as in Britain, and is regarded by many authors as a most irksome handicap.

Papers by J. Gardner Hopkins on the treatment of symmetrical lividity and hyperidrosis of the feet, by F. G. Novy, jun., on a severe form of acne developing in the tropics, and by Everett C. Fox on thermogenic anhidrosis revealed the interest which American dermatologists have taken in some of the problems they encountered during the war. Several contributions, particularly one by H. L. Keim, A. E. Palmer, and D. L. Frisch concerning plasma proteins and dermatitis, illustrated their concern with biochemical findings. J. H. Lamb, E. S. Lain, C. Keaty, and A. Hellbaum submitted a paper on the steroid hormones in dermatomyositis, lupus erythematodes, and polymorphic light-sensitive eruptions, and it was evident that their investigation is likely to bring us much valuable knowledge.

---

[3] Ontario Department of Health, Division of Medical Statistics: Survey of Public General Hospitals in Ontario, 1940.

J. F. Burgess, of Canada, contributed observations on the effect of vitamin E on collagenous tissue; his work may eventually connect with that of Lamb and his colleagues, and be useful both to the theorist and to the clinician. A different aspect of the biochemical approach to dermatology was shown by L. A. Brunsting and H. L. Mason in an inquiry into the relationship of porphyria and photosensitivity.

Interest in histology has not waned: H. Beerman's paper on hypertrophic Darier's disease and nævus syringocystadenomatosus papilliferus, C. W. Laymon and I. Fisher's paper on the diagnosis of necrobiosis lipoidica diabeticorum, and S. W. Becker's views on pigmented nævi were all ably discussed.

J. J. and W. D. Eller with J. W. Goldzieher reported studies of over 450 biopsies made to determine the cutaneous effects of local applications of natural œstrogens. They found that these caused epidermal proliferation. Comment on this communication was brisk, for apparently in America creams and ointments containing œstrogens are being used for purposes which are largely cosmetic. An eminent speaker summarised the opinion of most members when he said: "When a lady asks me if she should use creams of this nature I tell her that they will do her no good and may do her a great deal of harm." This is an obiter dictum which we may well adopt.

One authority used a method of presenting material which is not widely known in Britain. He had submitted a number of questions to several colleagues and had received a hundred replies. To display the answers he used lantern-slides, each of which showed the question followed by a statistical summary of the answers received. By this device the analyses of the answers to some half-dozen critical questions were rapidly conveyed to his audience, who were thus spared the fatigue usually engendered by the recitation of figures.

At the end of the meeting Dr. J. GARDNER HOPKINS was inducted to the presidency.

BIRTHDAY HONOURS

THE honours list issued on June 12 contains the following names of members of the medical profession:

P.C.

Sir GODFREY HUGGINS, C.H., K.C.M.G., F.R.C.S.
Prime minister of Southern Rhodesia since 1934.

K.C.B.

Surgeon Vice-Admiral HENRY ST. CLAIR COLSON, C.B., O.B.E., M.B. Lond.
Medical director-general of the Navy.

K.C.V.O.

Sir HUGH LETT, Bt., C.B.E., D.C.L., M.B. Vict., F.R.C.S.
Hon. secretary, King Edward's Hospital Fund for London.

Surgeon Rear-Admiral HENRY ELLIS YEO WHITE, C.V.O., O.B.E., M.D. Edin.

Knights Bachelor

WILLIAM NORWOOD EAST, M.D. Lond., F.R.C.P.
For services to the study of criminal psychology.

DAVID KENNEDY HENDERSON, M.D. Edin., F.R.C.P.
Professor of psychiatry, University of Edinburgh.

ERNEST LAURENCE KENNAWAY, D.M. Oxfd, D.SC. Lond., F.R.C.P., F.R.S.
Lately director, Chester Beatty research institute, Royal Cancer Hospital, London.

ALEXANDER MCCALL, M.D. Glasg.
For public services.

ARCHIBALD HECTOR MCINDOE, C.B.E., M.B. N.Z., M.S. Minn., F.R.C.S., F.A.C.S.
Civilian consultant in plastic surgery to the R.A.F.

Colonel GEORGE REID MCROBERT, C.I.E., M.D. Aberd., F.R.C.P., I.M.S.
Inspector-general of civil hospitals, Bihar; lately professor of medicine, Madras Medical College, and physician, Madras General Hospital.

THOMAS WILLIAM MEAGHER, M.B. Melb.
Lord mayor of Perth, Western Australia, 1939–45.

ROBERT ARTHUR YOUNG, C.B.E., M.D. Lond., F.R.C.P.
Consulting physician, Middlesex Hospital, London.

C.B.

Major-General WILLIAM FOOT, M.C., M.B. Dubl., K.H.P., R.A.M.C.

C.M.G.

JOHN MALCOLM, M.D. Edin.
Professor emeritus of physiology, University of Ota

Colonel PHILIP GRAHAM STOCK, C.B., C.B.E., M.B., F.R.C.P.
Medical officer, Ministry of Health.

C.I.E.

Colonel LLOYD KIRWOOD LEDGER, O.B.E., M.B., C.S., I.M.S.
Inspector-general of civil hospitals and directo public health, Central Provinces and Berar.

C.V.O.

GEOFFREY SYDNEY TODD, O.B.E., M.B. Sydney, F.R.C.P.,
Superintendent, King Edward VII Sanatorium, Midh

C.B.E. (Military)

Surgeon Captain ROBERT GREGORY HENDERSON, M.D. Ab R.N.V.R.

C.B.E. (Civil)

EDWIN ARTHUR BLOK, L.R.C.P.E.
Lately assistant director of medical services, Ceylo

GEORGE LINDOR BROWN, M.B., M.SC. Manc., F.R.S.
Member of the scientific staff of the Medical Res Council; for services to medical research in the F Navy.

HENRY ANSTEY COOKSON, M.B. Edin., F.R.C.P.E.
For public services in the county of Durham.

ERIC WILFRED FISH, M.D. Manc., D.SC. Lond., L.D.S.
Dental surgeon, St. Mary's Hospital, London.

CONRAD TRELAWNEY FITZ-GERALD, M.D. McGill.
M.H.O. for the department of public health and wel Trinity East, Newfoundland.

JAMES ANDREW GUNN, D.M. Oxfd, M.D., D.SC. Edin., F R
Chairman, British Pharmacopœia Commission.

SAMUEL THOMPSON IRWIN, M.CH. R.U.I., F.R.C.S.E.
Chairman, Northern Ireland Medical War Committe

ALDWYN BROCKWAY STOKES, B.M. Oxfd, M.R.C.P.
Lately member of the National Advisory Council o Employment of the Disabled.

KHONG KAM TAK, M.B.E., M.B.
For public services in the Malayan Union.

O.B.E. (Military)

Surgeon Commander EDWARD WILLIAM BINGHAM, M.B. D R.N.

Lieut.-Colonel CHARLES DAVID BRUCE, M.B. Edin., R.A.M.

Lieut.-Colonel FREDERICK GRACE SMITH, M.B.E.
Officer commanding, Ceylon Medical Corps.

O.B.E. (Civil)

VERNON FITZCLARENCE ANDERSON, M.D. Lond., C.M.S.
Senior medical officer, British Honduras.

Major HUBERT JOSEPH CURRAN, M.B. N.U.I., I.M.S.
Principal of the medical school, Darbhanga, Bihar.

Miss CATHERINE HARROWER, M.B. Glasg.
Member of the Glasgow burgh insurance committee.

DAVID WINN HOODLESS, B.SC. Lond., L.M.S.S.A., C.M.S.
Lately principal, Central Medical School, Suva, Fiji.

NORMAN HOWARD JONES, M.R.C.S.
Director, medical department, British Council.

Lieut.-Colonel ROBERT KELSALL, D.S.O., M.D. Lond.
Chairman, High Wycombe medical board.

KRIKOR SOLOMON KRIKORIAN
Senior medical officer, Palestine (honorary).

Miss SOO KIM LAM, L.M.S.
For public services in the Malayan Union (honorary).

DAVID JAMES MASTERTON MACKENZIE, M.B.E., M.B. Edin.
Director of medical services, Bechuanaland Protectorate.

WILFRED ERIC STANLEY MERRETT, B.M. Oxfd, C.M.S.
Acting principal of the medical school and lecturer in physiology, Nigeria.

PATRICK JOHN MONAGHAN, M.B. Lond.
Chief medical officer, Western Samoa.

Lieut.-Colonel WILLIAM THOMAS-TAYLOR, M.B. Belf., I.M.S.
Deputy director-general, Indian Medical Service (Stores).

M.B.E. (Military)

Major JOHN COLSTON BABBAGE, M.B. Manc., R.A.M.C.

M.B.E. (Civil)

RISHNALAL VITHALDAS ADALJA, M.B.
For public and social welfare services in Kenya.
aptain NUGENT DAVY JEKYLL, M.B. Camb., I.M.S.
Agency surgeon and medical officer, Chitral State Scouts, North-west Frontier Province.
OBERT SCOTT REID, M.B. Glasg.
Admiralty surgeon and agent.
ATRESTON HEWLEY WHARTON, M.R.C.S.
Medical superintendent, Leprosy Hospital, British Guiana.

A.F.C.

ing-Commander ROBERT MAYCOCK, M.R.C.S., R.A.F.

Kaisar-i-Hind Medal

iss CAROL JAMESON, M.D. Stanford, F.A.C.S.
Vice-principal, Missionary Medical College for Women, Vellore, Madras.

Reconstruction

NURSES AND STATE REGISTRATION

OUR CORRESPONDENT REPLIES

(OUR leader last week entitled Responsibility of the Nursing Profession draws the following comment from the author of the article published in this column on June 7.)

THE NEED FOR AN EXTERNAL STANDARD

Discussing the suggestion that every training school might be allowed to develop its own curriculum and give its own certificate under a system of central approval and recognition of training schools you say that "the chief objection to such a plan is that it might intensify the snob differences which—though the common State examination has done much to dispel them—still linger between different schools." The nurse from a famous London voluntary hospital, you maintain, would have a much better standing, when it came to applying for a senior post, than the nurse from a relatively obscure school; the training schools already differ far too widely in their standards.

But here surely is confusion of two different things. Considerations of snobbery may be relevant if it is alleged that social status rather than merit determines admission as a student, but to suggest that it is likely to intensify "snob" distinctions if some schools are encouraged to go ahead and surpass others, and the students thereby attain prestige, is—let us be quite clear about this—to argue for a levelling down to a dull uniformity of mediocrity. This form of argument is only too common today, and it is already recognised in many quarters to be responsible for serious blunders in the field of secondary education. Progress implies difference, and the remedy is so to arrange the machinery as constantly to raise the standard of the backward without introducing a drag upon those that lead. The very fact that after twenty-seven years of State registration as now operated it can still be said that the training schools "differ far too widely in their standards" is evidence of the bankruptcy of the present system. It is far from clear that "the common State examination has done much to dispel them." Surely in the educational field we are not to aim at a system which shall rein back the leading schools in order not to prejudice the prospects of those who are not so fortunate as to gain admission to them? Rather a campaign should be waged against this popular misapplication of democratic thinking whenever and wherever it rears its head.

You may say, however, that you were not advocating uniformity, but, as you put it a little further on, urging that the public "deserve to know that a S.R.N. has carried out a given set of duties, just as they deserve to know that a doctor has had to cover certain well-recognised ground before he is allowed to register." Two things need be said on this. First, beware of the comparison with the doctor on the point of registration vis-a-vis the public. It is well to remember Miss Nightingale's vigorous and formerly well-known observations on this subject; she was wide awake to the dangers of this analogy. Secondly, though there is undoubtedly a need for some guarantee of a standard external to the training school, it is by no means clear that the present system achieves a desirable result. It does enable the nurse who comes from the little-known training school to claim that she is at any rate S.R.N. But if the S.R.N. is attained only by a process of cramming, as it often is, is it right and desirable that the external standard should count for more than the considered opinion of the training school? What of the girl who has concentrated on her patients rather than on cramming for "the State"? It is relevant to ask whether the present system does not achieve even this doubtful result at too heavy a cost in losses by the wayside, and only by diverting attention away from "training" to "examination tests."

It should not be taken for granted that a diversity of standards in different training schools will automatically lead to a lowering of standards in the less advanced schools, with a corresponding loss of prestige attaching to their certificates of proficiency. We are not comparing the present system with one in which common standards are non-existent (as they were before 1919), but with an alternative system which replaces the central examination by new machinery better adapted than the present to secure an all round upward movement. Standards, and effective standards, there must certainly be.

A UNIFORM GROUNDING FOR ALL?

Your leader refers also to the importance of making sure that all entrants get a thorough and uniform grounding in bedside nursing. So far so good; all will agree about the importance of this, but you then seem to lean towards the idea that all entrants should begin in the ranks and be selected for further training on their merits. The idea of a two-year "basic course" has been widely and influentially advocated, and it is a separate aspect of the subject which itself requires more serious consideration than it has so far received. There are perhaps two main difficulties and dangers.

First, there is the point touched on in your leader—that educated and intelligent girls would be put off if asked to undergo a simple practical course comparable with that now offered to the assistant nurse. You say that some senior public-school girls readily agreed that they would find practical work stimulating as a change, and agreed too on the importance of equal opportunity for all. This reaction is entirely intelligible, but the point cannot be so easily dismissed. The headmistresses and careers mistresses of our schools—and intelligent parents too—are already inclined to look on nursing as a career for those not quite equal to the more exacting standards required by careers such as medicine or teaching. Anything that tends to harden this attitude will adversely affect the recruitment to nursing of the most able girls. If a two-year basic course obligatory on all entrants increased the numerical entry it might well be at the cost of a fall in quality, a tendency which is already apparent and which it is of the utmost importance to correct. We need the numbers—is there a way out of this impasse? The problem and the difficulty surely spring from the conception of over-all uniformity, which since 1919 has dominated our thinking: allow diversity, and there will then be schools calculated to appeal to the able as well as others adapted to those of a more practical or domestic type.

The second danger is of a narrowing down of the conception of practical bedside nursing. It is beginning to be supposed that a nurse can be trained in all that really matters in a relatively short time, and that the more advanced part of a nurse's training consists of the acquisition of a theoretical background and a knowledge of various special subjects, which can safely be relegated to a more advanced course. This is surely open to the gravest doubt—does it not imply a false conception of the very essence of good nursing? In our best training schools the two things proceed together, but right through the emphasis falls on a progressive development of those qualities of personality—intuition, observation, understanding, and power to comfort the patient—which in the last resort determine the quality of the nurse. From first to last the essential thing about a nurse's training is the bedside, and bound up with it a progressive transfer to the nurse of responsibility for the patient's welfare; all else should be subservient to this end. To confuse these fundamental things with the acquisition of a knowledge of "practical nursing"—i.e., the simpler bedside techniques which alone can be adequately absorbed in a shortened course—is indeed to open the door to a lowering of standards in the essentials, and to diverge radically from the central tradition of British nursing at its best.

To say this is not to ignore the need for some modification of the present arrangements, nor to deny that a simpler shorter course is all that many candidates can profitably absorb. The catch in the reasoning occurs only at the point where it is suggested that all should qualify by the one route. The difficulty can be met and both objectives achieved as soon as the conception of uniformity is replaced by that of diversity.

Public Health

Smallpox

CONTACTS remain under surveillance at Barnsley, Bilston, Staffs, and Wakefield. The last patients were removed on June 1 and the cropping period for a new generation has been entered, but no further cases had been reported up to June 17.

At *Barry, Glamorganshire*, a woman, aged 28, was removed as a case of suspected smallpox on June 13, and the usual precautions were taken. The diagnosis is still in doubt.

Wakefield.—The diagnosis in the initial case has now been confirmed by the recovery of variola virus on egg culture.

Sheffield.—The last case was removed on May 21 and there are good reasons for believing that the outbreak has terminated.

Coseley, Staffs.—The period of surveillance of contacts expired on June 16 without further incident. The outlook here is hopeful.

Infectious Disease in England and Wales

WEEK ENDED JUNE 7

Notifications.—Smallpox, 7; scarlet fever, 730; whooping-cough, 2050; diphtheria, 196; paratyphoid, 16; typhoid, 2; measles (excluding rubella), 13,535; pneumonia (primary or influenzal), 407; cerebrospinal fever, 63; poliomyelitis, 22; polioencephalitis, 2; encephalitis lethargica, 4; dysentery, 53; puerperal pyrexia, 128; ophthalmia neonatorum, 75. No case of cholera, plague, or typhus was notified during the week.

Of the smallpox cases, 4 were notified at Bilston, Staffs, 2 at Barnsley, and 1 at Wakefield.

Deaths.—In 126 great towns there were no deaths from enteric fever, 1 (0) from scarlet fever, 2 (0) from diphtheria, 1 (0) from measles, 11 (2) from whooping-cough, 71 (9) from diarrhœa and enteritis under two years, and 2 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 235 (corresponding to a rate of 21 per thousand total births), including 31 in London.

In England Now

A Running Commentary by Peripatetic Correspond

HAVING been summoned to the Royal Garden
we set off from our suburb soon after lunch in a
Daimler, in an aura of moth-balls and envy. The f
seemed to be associated with my pre-war "mo
attire" and topper; the latter with our neigh
who could be seen peeping from behind every curt
the road.

It was pleasant to stroll about the sunny lawns c
Palace feeling rather well dressed, and with none c
feeling usual in such circumstances that the prole
are observing and disapproving. The King in
uniform walked with Princess Elizabeth slowly th
the crowd, being introduced to selected swells and
ing those they know. The Queen and Princess Mar
did the same in another part of the garden. Both p
were unobtrusively shepherded by suave and eff
officials of the court. This interesting genus of "
room boy," in common with editors and many p
logists, delights to exert its beneficent influence
behind the scenes rather than in the rough and tu
of life. There seems to be an increasingly good ca
this modus operandi in modern life.

Rather to our surprise the Faculty seemed t
extensively represented. Apart from the royal physi
and others of that calibre, who could be seen from
consorting with "Winnie" and the other celeb
in the paddock, a galaxy of lesser lights were disco
in the refreshment tent making considerable in
on the iced cake (real icing!) which was subsequ
agreed by all to constitute a proper priority or
attention. A disappointing break with tradition
the absence of strawberries and cream, but a po
and exotic novelty was the coal-black band of
Gold Coast police, who finally played us out to
strains of God Save the King at six o'clock. Lat
the local, we voted it a very pleasing alternative t
normal afternoon's work.

* * *

Falmouth—there's a fine town for you. Big o
going ships in the docks, quite still while the cla
metal never stops; tall houses and warehouses
out of the sea itself, with steps leading down to the
oily water of the harbour; tugs and ferries hooting
fussing and ignoring the liners which tower above th
the pub, which has seen better days, its gallery pu
out across the narrow street; the swarthy Indian
Glasgow-Irish, the Fez, and across the water
smooth lines on the horizon of the distant fields
hills, their colours especially beautiful in early s
because of the young corn and the reddish-b
earth.

But all this is in the guide-books. Step away from
traffic for a moment and climb one of those tort
streets which lead up through the old town to the s
Visitors who venture this way soon return, most of
with an uneasy feeling that slums like these ought
to be found on the Cornish Riviera. But there they
and as bad as any to be found in a northern city, ex
for the sun and stone and strange precipices. Tum
together in a fantastic disorder, one house above ano
attics where cellars should be, crazy steps clim
between high walls past drunken gas-brackets,
Italian hill-town shows unforgettable pictures in ston

Sitting in the warm sun of March I saw an old
slowly and laboriously puffing his way up the st
my greeting gave him an excuse to stop, and smilin
told me how much Falmouth had changed during
65 years his memory had retained. "Three
I've seen, and each one worse 'n last"—but how pro
he spun the yarn of that night when the bomb lan
uninvited outside his house at three o'clock in
morning, and covered his bed with glass.

Gone are the days when one could buy as much m
for Saturday dinner as one now gets in a month. S
the children looked happy enough playing with the d
in the streets; healthy and dirty, their shouts ech
behind me as I followed my winding road to the st
below. Here's the rub: out of these houses, unfit

ogs to live in, come people vigorous and lively and aceful; “patchwork” rebuilding would be impossible this forest of stone. Must the old town be razed to e ground and replaced by rows of utility houses, or ould the example of Carcassonne be followed, leaving dead beauty, emptied of its wild-living children and its wn-ups sitting on the doorstep in the sun and talking the neighbour? No doubt, this being Cornwall, and en *England* (though the *Cornishman wouldn't thank* ou for telling him so), a compromise will be found, the ms slowly becoming less dark and dirty, the houses dually losing their impossible dream-like quality. less perhaps the first atomic bomb. . . . Well, anyhow. 's a fine town, and the people who live there are quite htly proud of it.

* * *

They had eased their steeds from a breath-taking llop and now were jogging quietly along together. ey both seemed unconscious of the fact that the ound beneath them was pitching to and fro as if from ne volcanic upheaval, and that a damsel in distress d released herself from a monster which had been rforming ruderies on a tender portion of her anatomy d undaunted was about to mount a camel.

“I'd like to see a whale,” remarked one of them flectively. “What *about a bicycle ride?*” said his mpanion. They changed their steeds and rode a arter of a mile. The girl rowed beside them; she asn't good with her oars, and the sliding seat kept ming off its rollers. “It's a great consolation to ow we are in a rough sea,” she said, “I was sick all is morning.” They decided that a trick cyclist was eded to study the problem. There were people who ankly said without shame “I've been sick.” Others vented all kinds of excuses: “I slept in a draught st night and I've got a chill; a couple of aspirins will on put me right.” Others again wouldn't give in; ey came down to meals and went away looking green; went to the cinema and were suddenly sick on the or. “Interesting problem, sea-sickness,” said the an who wanted to see a whale. “I'll have to go and ange for dinner,” said his friend.

They got off their bicycles and walked away, staggering s they went, for the ground still heaved beneath their et.

“I hate surrealism,” said one of them, inconsequentially, it's so adolescent. This”—he waved his hand to dicate the broad wastes of mid-Atlantic—“is so real.” e door of the ship's gymnasium shut behind them.

* * *

Sitting and thinking—in the intervals of just thinking which is occasionally the anæsthetist's lot, I realised ow beautifully your surgical peripatetic correspondent May 31 had classified us. He has even moved me to tempt a similar classification of surgeons, lest the onderful?) day should come when the positions are versed and *our* secretaries have to telephone the surgeon give him time, place, and details of the little job we e asking him to do on *our* patients.

* Never rude or sarcastic (not even to nurses). Doesn't ant to control the drip. No gross errors of technique. Safe n lipomas and bunions.

** Even temper. Reasonably punctual. Doesn't give us n an anatomy *lecture every time*. Supplies postoperative rlick's for whole surgical team.

*** Seldom appears to be in a hurry. Deigns to come to his n telephone when possible. Gentle below the diaphragm. oesn't demand the fourth plane of the third stage for all dominals.

**** Instant assumption of responsibility for spasm and/or ughing and/or cyanosis and/or movement. He knows, and know, that this was caused by my preoccupation with (1) the full” cylinder which has turned out to be empty; (2) the ancet; (3) the probationer's legs. For lady anæsthetists ad: (1) ditto: (2) *Vogue*; (3) whatever may be the male uivalent; I wouldn't know.

Each lot of course possess the virtues of the less starred tegories besides those of their own class, and needless say anyone not possessing the basic virtues has not en one star—that is, he has been struck off our list ltogether.

Letters to the Editor

THE STUDENT AND THE ALMONER

SIR,—It has often been suggested that medical students should spend some part of their training under the supervision of a general practitioner in order that they should learn something of the personal and domestic problems which form the social environment of illness as it primarily hits each one of us. Many of us who are in general practice are interested in the idea, but are all too well aware of the difficulties involved.

Has it ever been considered possible to utilise the social services already available in all the teaching hospitals? During the time of medical or surgical clerking why not assign the student for a certain period to the department of the hospital almoner? Let the student take charge of a case specially selected by a trained and experienced almoner. Let him study the whole social set-up of the case, investigating especially those factors which may have contributed to the development of the illness, and those problems which the illness has produced for the patient and his family. Finally let him visit the patient after he has returned to his home.

Such a scheme would give students invaluable insight into the personal and domestic difficulties met constantly in general practice, and would help them to realise the extent to which illness, as met with in the home, is primarily a social question in a large number of cases. Even if the complexities of the curriculum make it impossible for students to perform these social services for more than a single case, I feel it would still give them experience of a sort which is now obtainable only when they go into general practice.

London, S.W.10. A. E. BERYL HARDING.

SUCCESSFUL REVACCINATION

SIR,—I have read with great interest the various recent articles on smallpox vaccination in THE LANCET, particularly those by Dr. Broom (March 22) and Dr. Mitman (April 5). Both have served a good cause by calling attention to the difficulty in interpreting the “immune reaction” and by pointing out the danger of regarding such a reaction as ipso-facto evidence of immunity to smallpox. However, the suggestion by Dr. Broom that certain individuals are “*insusceptible*” to vaccination and should be certified as such, and the assertion by Dr. Mitman that the immune reaction is only a reaction of sensitivity, appear to me to represent misconceptions which are potentially dangerous and therefore call for further analysis and comment.

If one rearranges Dr. Broom's data so as to show the *percentage* of individuals manifesting each type of response to vaccination, one obtains the following figures:

	Years since last vaccination					
Reaction	*0–2*	*2–5*	*5–10*	*10–15*	*15–20*	*20*
Primary and accelerated	47%	57%	68%	71%	71%	83%
Immune	40%	21%	9%	0%	3%	<1%
Nil	13%	22%	23%	29%	26%	16+%
Control	9%	13%	11%	11%	14%	6%

It is clear that the percentage of “susceptibles” (primary plus accelerated reactions) correlates directly with the interval since last vaccination (as one would expect), whereas the percentage of immune reactors shows an inverse correlation, as one would also expect if the respective types of reaction mean what they are usually thought to mean. On the other hand, neither the group showing “no reaction” nor the various subjects exhibiting a “control reaction” show any such correlation, direct or inverse, but instead vary throughout all groups within a rather narrow range. This would suggest that both types of reaction are independent of immunity, and depend upon one or more unrelated and relatively constant factors.

The inference from these data, and the one which appears to accord best with the other known observations regarding vaccination, would seem to be as follows:

1. The *primary reaction* results when vaccinia virus invades and multiplies vigorously in a completely susceptible host.

2. The *accelerated reaction* represents an infection which is more rapidly brought under control by a partial host immunity which may vary considerably in degree and which in turn must be considered in relation to the invasive potency of the particular virus preparation employed.

3. The *immune reaction* occurs when the host-immunity level is sufficient to suppress the particular virus infection in question before it gets fairly started: thus the chance of producing such a reaction is favoured not only by a very high immunity level in the host but also by a relatively low degree of infectivity of the virus.

4. The immune reaction may be closely simulated by a reaction due to a sensitivity which, as Scott and Warin recently reported,[1] is apparently elicited by the constituents of vaccinia virus, much as the reaction to heated diphtheria toxin may simulate the Schick test.

5. The "nil" reaction—i.e., absence of any reaction—shows no correlation with immunity or susceptibility, and must be regarded as indicating only that effective penetration of the host tissue did not take place; here revaccination is indicated no matter how many "failures to take" the patient has already experienced. Certification of such individuals as "insusceptible" will not prevent them from subsequently contracting smallpox when exposed.

The number of "immune"—or, if you will, "uninterpretable"—reactions may be reduced by the use of a more potent vaccine, as has been shown by Horgan and Haseeb [2] and others. Furthermore, Horgan and Haseeb stress the danger of obtaining weak reactions to revaccination if a single scratch technique is used. The multiple-pressure technique of vaccination, if properly performed, has been widely observed to give more consistent "takes" than the scratch method. This may be due to the increased chances of penetrating to a suitable depth if multiple separate breaks in the skin are made, as noted recently by Mole.[3] Thus the multiple-pressure method may have additional advantages to those already pointed out by Parish.[4]

Boston, Mass. GEOFFREY EDSALL.

STEVENS-JOHNSON SYNDROME

SIR,—The recent articles in THE LANCET were of great interest here since they arrived during the convalescence of the case reported below, which at the time was regarded as an unusual case of erythema multiforme.

A soldier, aged 21, was admitted on March 28, 1947, complaining of sore throat and cough with watery sputum for 6 days. For a month he had had a mild dry eczematous dermatitis of both forearms, but during the previous 2-3 days a different rash had developed, consisting in small circular scaly erythematous patches which coalesced in places. These were numerous on the forearms and there were a few on the trunk. On the day after admission a severe stomatitis, conjunctivitis, and balanitis developed. The mouth was covered with a peeling greyish membrane, and the pharynx was red and injected. Three swabs from the mouth showed no Vincent's organisms, and from the throat *Streptococcus viridans* was grown. The conjunctivitis was very severe; swabs showed numerous pus cells, but no organisms were isolated. The glans penis was red, and the skin was weeping and peeling. A white blood-cell count at this stage showed 19,500 leucocytes, of which 90% were polymorphs, 8% lymphocytes, and 2% monocytes. Sputum examination showed numerous pus cells, and no one organism was predominant on culture.

The patient was very ill and toxic. He could only swallow fluids, and even this was difficult. On examination of the chest moist râles were heard all over both sides. The temperature was swinging between 101°F and 103°F. On the second day the skin lesions became bullous with purplish edges, and a diagnosis of erythema multiforme was made. The temperature subsided almost to normal by the 7th day, although the mouth and eyes were still severely affected. The bronchitis was still severe, a pint of frothy mucopurulent sputum being produced each day. The skin lesions had increased in number and were chiefly on the back and arms. The lips were grossly swollen and cracked, and the patient could hardly speak.

By the 26th day he was almost well. The conjuncti was improving and all that remained of the skin lesions brown pigmented patches. A stricture of the foreskin developed as a result of the inflammation.

Swabs taken from the bullous skin lesions gave no or on culture; nor did swabs from the penis. It was not to decide whether there was a pure urethritis owing severe inflammation and swelling of the glans and pre

The patient had an uninterrupted convalescen when last seen six weeks after discharge from h he was well, except for the occurrence for the fir of psoriasis on his arms and trunk. The pigme of the skin remained. Penicillin was administered the early stages of the disease, but did not se influence its course.

FATAL CEREBRAL INJURY IN BOXE

SIR,—The following case, investigated by per of Major-General R. J. Palmer, D.S.O., Commissi the South African Police, is of interest in illustrat possibility of fatal injury to boxers.

A 23-year-old professional boxer participated in a fight under the auspices of the Board of Control for Prof Boxing and Wrestling, which had satisfied itself t requirements framed under the Act in force were o and that the tournament was carried out strictly in acc with the Act. An honorary medical officer of the examined the boxer before the fight and testified that medically fit to go into the ring. After the fight the said that the blows were all legitimate and there was foul in them.

The boxer was knocked down in the first round b at the count of five. At the beginning of the fourt he was again knocked down but was on his feet just be referee could count ten. Half a minute later he was s heavy blow on the left side of the jaw which knocked h He was unconscious for the next six days except for three brief lucid intervals.

Immediately after the knock-out he was admitte hospital where intracranial hæmorrhage was diagnose emergency trepanation was performed and a right su hæmorrhage drained. As the patient did not rally a operation was performed a week later and more su blood was evacuated. However, death ensued about a fo afterwards. Post-mortem examination revealed so blood-clot adherent to the inner surface of the dura as well as the presence over the left cerebral hem of purulent meningitis, which was found to be staphylococcal infection.

A case of subdural hæmorrhage in a 15-year-ol who had been knocked out while boxing was re by Voris.[1] When burr holes were made in each p occipital region, a liquid subdural hæmatoma of mo size, with well-developed neomembranes, was re on the left side.

Johannesburg, S. Africa. E. J

CONTINUOUS INTRAVENOUS INFUSION

SIR,—Dr. Walton's article (May 17) gives a t reminder that the irritating difficulty of maint the constant flow of a drip transfusion is not alway to resistance in the veins. Walton states that no for slowing and arrest could be found; but it c shown that the screw clip on the rubber tubing cont the inflow of the interceptor is the trouble. The u bility of this part of the apparatus is readily demons by observing the outflow from a simple rubber attached to a reservoir, and constricted by a screw Under these circumstances there is no *constancy* in the rate of flow or in the change of rate. Generall flow lessens, but after decreasing it may increase a The variations appear to be due to the rubber tu and not to slipping of the screw clip since there perceptible movement of the screw head during slo this can be corrected only by rotation of the through several degrees.

Further proof that the slowing is due to the cli tubing is afforded by the observation that if the is regulated instead by a capillary resistance the

ral Infirmary, Manchester.

ACADEMIC FREEDOM

R,—I think that Dr. Richard Doll (May 17) and others effectively disposed of Professor Polanyi's philo- ical arguments regarding the future of science. But ould like to raise a few further points, and also to est an alternative way of controlling scientific work he future.

rofessor Polanyi presents us with the picture of this being, the scientist, perched on his seat of know- e far removed from the coarse realities of the world oday. Let this mundane world outside use his pure wledge as they will. For *even if this means mass* nction of the human race in atomic warfare, the ntist must remain aloof in his ivory tower, uninfluenced material considerations. Unfortunately, if whilst ying this pipe dream he should discuss his particular e of the jigsaw of knowledge with colleagues working he same field, he may find himself transcended to ore mundane tower in company with Dr. Nunn May. he object of all this phantasy is clear. Polanyi eats from the fact that scientists are increasingly g forced by the implications of their work to realise t they have a social function, good or evil. With social function go social obligations and the realisa- that ultimately their work is meaningless unless ely linked with that of the society in which they and work. Perhaps more important still, they are easingly coming to realise that the two apparently osite poles of pure and State-applied science can be thesised. For the scientist in fully participating as active member of democratic society exerts the hest form of control over his own work in a planned iety.

hose who, like Professor Polanyi, obscure this real e are, consciously or otherwise, accentuating the os in our era.

ondon, S.W.15. H. C. PRICE.

DENTAL CARIES

IR,—Dr. Neumann's letter of June 7 strikes me as most valuable and convincing summary of evidence brought together. When years ago I asked the late lliam Bulloch, the distinguished bacteriologist, as to value of toothbrushes and dentifrices for preventing ay, he said "they only help to spread the trouble." e evidence then is that, apart from some slight metic value, the many thousands of pounds spent these are useless.

halfont St. Peter, Bucks. LEONARD HILL.

A RECORD LOW HÆMOGLOBIN

IR,—We were interested in the letter of Dr. Karani l Dr. Szekulesz in your issue of June 7 because we l recently seen another case of extreme anæmia.

n May 19, 1947, a woman, aged 63, was admitted to this pital in a comatose condition. Complaint was of increasing kness for eight months. She was extremely pale, with a on-yellow tint of the skin, but was reasonably nourished. was restless and her respirations were deep and irregular: tongue was smooth and shiny, hair and nails normal. ere was slight œdema of the ankles. The liver was just pable below the costal margin and the spleen impalpable. art, chest, and nervous system normal. Temperature 2°F; pulse-rate 90 and respirations 28 per min. B.P. 110/80 a. Hg.

The blood picture on admission was: Hb 1·5 g. per 100 m.; colour-index 1·5; P.C.V. 5%; M.C.V. 150 c.µ; red ls 330,000 per c.mm.; M.C.H.C. 30%; reticulocytes 0·5%. ere was a faint icteric tinge of the serum. Blood film showed crocytosis, anisocytosis, poikilocytosis, and polychromasia. e bone-marrow withdrawn by sternal puncture showed negaloblastic reaction with several early megaloblasts.

Half a pint of packed cells (blood-group A2) was given by w intravenous drip on admission and subsequently daily for the next three days, with dramatic improvement in the patient's condition. 'Anahæmin' 4 c.cm. was given parenterally on May 20 and 21 and twice weekly since then. Penicillin 50,000 units intramuscularly thrice daily was given for the first eight days prophylactically.

On May 27 the blood picture was as follows: Hb 7·45 g. per 100 c.cm.; colour-index 1·32; P.C.V. 27%; M.C.V. 114 c.µ; red cells 1,925,000 per c.mm.; M.C.H.C. 27·6%; reticulocytes 10%. Temperature was then 97·4°F, pulse-rate 84 and respirations 20 per min.

This is undoubtedly a case of pernicious anæmia which had been allowed to go untreated. The condition was aggravated by the fact that the patient has gross external hæmorrhoids which bleed intermittently. Her general clinical improvement is maintained at the time of writing.

Southern General Hospital, P. BARRON
Glasgow. R. McL. ARCHIBALD.

PROPYL THIOURACIL

SIR,—In their paper of May 17 Dr. Wilson and Dr. Goodwin have compared the action of propyl thiouracil introduced by Astwood et al. in 1945[1] on account of its higher potency and possible lesser toxicity, with the effect of thiouracil and methyl thiouracil.

I have compared in 6 patients the effect of methyl and propyl thiouracil (the latter kindly supplied by Messrs. Genatosan Ltd.). I noticed some interesting points of distinction between the two products which, I believe, are worth communicating.

I can confirm Wilson and Goodwin's observation that the lag period between start of treatment and response was not shorter with propyl than with methyl thiouracil. In one patient who had been on iodine before and who was given up to 250 mg. of propyl thiouracil per day, it was a month before subjective improvement and definite slowing of the heart-rate set in.

Astwood found that in the rat propyl thiouracil was ten times more potent than methyl thiouracil; and Wilson and Goodwin conclude that the former is about four times as potent as the latter. Nevertheless, they had to give 25–75 mg. of propyl thiouracil as daily maintenance dose—dosage similar to that advocated by Astwood and Vanderlaan[2]—whereas the normal maintenance dose of methyl thiouracil is 25–100 mg. per day. By varying the doses and interchanging methyl and propyl thiouracil in my cases it appeared that doses smaller than 25–75 mg. of propyl thiouracil are liable to cause relapses and that the potency of propyl thiouracil is only about two to three times that of methyl thiouracil. From my own, limited, experience I have come to the conclusion that 150–250 mg. of propyl thiouracil per day is necessary to control the acute case, and I think that such a dose should be recommended with this compound, according to the severity of the case. As 400–600 mg. of methyl thiouracil per day has previously given me similar good results, especially if spread over the day in small doses,[3] propyl thiouracil seems again to be only two to three times as potent as methyl thiouracil in the dosage necessary for treatment. There were no toxic reactions among the small number of cases treated by me.

Two striking differences between the two thiouracil derivatives could be noted. The first, also observed by Wilson and Goodwin, was that no noticeable thyroid enlargement developed after propyl thiouracil with the doses employed. This may be due to the dosage, but a conspicuous reduction in the size of the thyroid gland was noted in 3 patients when they were switched over from a maintenance dose of 100 mg. of methyl thiouracil to 75 mg. of propyl thiouracil; the difference in dosage appears too small to account for this observation. I believe that the absence of thyroid enlargement is important, since the large goitre which sometimes develops after methyl thiouracil may cause pressure symptoms, especially in cases of retrosternal goitre.[3]

The second point, not mentioned by Wilson and Goodwin but very pronounced in all my cases, was the

QUESTION TIME

Medical Certificates

r. John Morrison asked the Minister of Health if he ld give a list of all the certificates required by Government rtments which a doctor might be called upon to sign on lf of a patient.—Mr. A. Bevan replied: Medical certifi- may have to be produced by patients to Government rtments under the following enactments or for the follow- rposes. This list is not necessarily exhaustive.

Under the Births and Deaths Registration Acts, 1836–1926—to certify cause of death to the Registrar.

To assist in determining a claim to war pension or allowance.

Under the Lunacy and Mental Treatment Acts and the Mental ency Acts.

In support of claims to benefit under the National Health ance Act, 1936, and the contributory Pensions Acts, 1936–41.

In support of sick absence by a Government department as oyer.

Under the Blind Persons Acts, 1920 to 1938, to support pplication for old-age pension at 50.

Under the Essential Work Orders, Control of Employment ated Persons) Order, 1943, and Control of Engagement Orders pport of a claim to leave or change the employment.

Under the Road Haulage Wages Act, 1938, the Catering es Act, 1943, and the Wages Councils Act, 1945, in support ermit to be employed at sub-standard wage-rates.

Under the Coal Distribution Order, 1943, and the Control uel (Restriction of Heating) Order, 1947, to obtain additional lies of fuel and exemption from heating restrictions.

Under the Disabled Persons (Employment) Act, 1944, for tration.

Under the Corsets (Manufacture and Supply) (No. 14) ctions, 1946, to assist in obtaining surgical corsets.

Under the Welfare Foods Order, 1946, to enable expectant ers to obtain food benefit.

Under the Rationing Orders or otherwise to enable invalids btain special authority for supplementary rationed food and to invalids, expectant mothers, and others to obtain special tment with regard to goods which are the subject of Government rol.

Under the Control of Motor Fuel Orders to assist claimants dditional petrol allowances on medical grounds.

Under the National Service Acts, 1939–1947, in support of aim for exemption from, and to justify failure to comply with, isions of the Acts.

Under the Cremation Act.

Notification of Rubella

r. S. Hastings asked the Minister whether, in view of the easing birth-rate and the clear evidence that german sles in the mother could produce serious defects in the born child, he would make this a notifiable disease, so that cautions could be taken to prevent its spread to those t liable to be adversely affected by it.—Mr. Bevan lied: The effects of this disease in pregnancy are being stigated in conjunction with the Medical Research ncil, and perhaps my hon. friend will let me have the dence he refers to. I should prefer to await the results of investigation before considering the matter further.

On the Record

Replying to a question, Mr. A. V. Alexander stated that dical examinations in the Naval Forces included miniature iography of the chest when a person is entered, or as n as practicable afterwards, and thenceforth periodically far as staff and equipment allow. A "follow-up" system luded full-scale films and special observation treatment hospital of cases of doubt; all drafting of persons concerned stopped for such period. Over 90% of Army recruits re examined by mass radiography to detect primarily the sence of pulmonary tuberculosis. As soon as enough ff and equipment were available all recruits would be so amined. In the Royal Air Force all recruits had a chest ray as a matter of routine. Further chest X-rays were anged as required. The facilities would be developed ther as and when skilled personnel became available. inter-Service committee on medical documentation had ently been appointed to consider the possibility of intro- cing a common system for the three Services, on the most -to-date lines, bearing in mind war experience not only in s country but also in Germany and the United States.

Empire Reciprocity in Social Insurance

Mr. Charles Smith asked the Minister of National Insurance at steps had been taken by His Majesty's Government make reciprocal arrangements with the Dominions with view to ensuring that elderly persons were not disqualified from pensions in this country on the ground that they had been resident in the Dominions.—Mr. James Griffiths replied: A preparatory conference of officials, representing the Governments of the United Kingdom, Canada, Australia, New Zealand, South Africa, Eire, and Southern Rhodesia, with an observer from Burma, sat in London last month to examine the principles on which reciprocity in the field of social insurance might be based. I am glad to say that the conference was able to frame a unanimous report. This will be submitted to the governments concerned and will I hope provide a basis for the consideration in due course of agreements for reciprocity between individual countries whose social service schemes have the necessary common ground for such arrangements.

Employment of Epileptics

Mr. H. W. Bowden asked the Minister of Labour if he was aware that there were numbers of epileptics registered as unemployed in the United Kingdom; that many were unable to obtain employment because of their disability; and if he would consider ways of getting these people to work in the open air under medical supervision.—Mr. George Isaacs replied: The latest available figures indicate that about 1350 epileptics are now registered as unemployed. The problem of finding suitable employment for epileptics has recently been the subject of special study in my department, in conjunction with the medical authorities. There are many occupations, including some in the open air, which are suitable for them, and every effort is being made to place the less severely disabled of them in such jobs with sympathetic employers, and some of the more severe cases have already been placed in employment under sheltered conditions.

Lister Institute

Mr. S. P. Viant asked the Minister of Health whether it was intended that the Lister Institute of Preventive Medicine should be controlled by his department when the National Medical Service Act came into operation; and what was the present relationship between the institute and his department.—Mr. Bevan replied: The Lister Institute is a non-profit-making institute which, like other manufacturers of therapeutic substances, holds licences from the Minister of Health under the Therapeutic Substances Act to manufacture certain substances to which the Act applies, and by special arrangement provides for the Minister supplies of lymph required for public vaccination against smallpox. The National Health Service Act will not affect the relation of the institute to the Ministry.

Colonial Medical Research Service

Sir Ernest Graham-Little asked the Secretary of State for the Colonies why candidates for the proposed Colonial Medical Research Service had been kept waiting with promises of engagement, but without definite appointments and without salaries, in many instances up to six months.—Mr. Creech Jones replied: I am aware that it has taken much time to settle the conditions and terms of service of the proposed Colonial Research Services, but that has been due largely to the very novel problems raised by the attempt to fit officers in an exceptional position into the established practices of the public services. I cannot accept the suggestion that a large number of officers have received promises of appointment from a responsible authority and have then been kept waiting indefinitely for their actual appointment.

Food for Invalids

Mr. L. D. Gammans asked the Minister of Food for what reasons his department overruled the recommendation of her family doctor that a patient should receive extra meat and butter by substituting milk which, in her case, was actually harmful; why this decision was taken without consultation with her medical attendant; why two months' delay took place between the issue of the certificate and its refusal by the divisional food office; and what steps he proposed to take to prevent a recurrence of such a delay with its possible harmful effects.—Mr. J. Strachey replied: This case was considered twice during the two months by the Special Diets Advisory Committee on different certificates from the family doctor, but she was unable to produce any reasons for the suggestion that the usual allowance of milk would be harmful or that there were any special reasons for an allowance of butter and meat for this particular

system for the ascertainment of truth, though costly, s unsurpassed and should be preserved. Sir Maurice ly said that the two callings were united in the splendours their antiquity; no one in either profession wished to leave [illegible] cause those uninterested were quickly eliminated by examiners. Toasting the Society, Lord Moran ed that the essential difference between the outlooks ctor and lawyer lay in the fact that though both were ned with the truth, the doctor answered questions ly, supporting his replies with objective data, whereas lawyer sought that aspect which was most favourable to client. Dr. Norwood East spoke of the society's growing gth and of the need to maintain its high standard, and C. Thackray Parsons paid tribute to it for helping the n in the dock by studying the roots of crime.

---

iversity of Oxford

On June 7 the degree of D.M. was conferred on Margaret ies.

iversity of Cambridge

On June 7 the following degrees were conferred:

M.D.—J. W. D. Bell, G. S. Graveson, J. H. Humphrey, H. S. [illegible], *Man Wong.
M.Chir.—R. L. Canney.
M.B., B.Chir.—* G. H. P. Drake.

* By proxy.

Public Health Laboratory Service.—Dr. R. M. Fry has been inted university director of this service and Dr. Joan eard assistant-director. The service is associated with department of pathology and the director will assist the fessor of pathology in research and teaching.

University Health Service.—The university is inviting lications for the whole-time posts of senior and junior th officers whose chief duties will be the medical examina- n of undergraduates. The posts will carry yearly salaries £1000 and £700.

yal College of Surgeons of England

At a meeting of the council held on June 12, with Sir red Webb-Johnson, the president, in the chair, it was unced that *a supplemental charter had been granted to* college, giving power, among other things, to coöpt itional members of the council, to conduct a special l fellowship examination in ophthalmology and otolaryn- gy, to grant a fellowship in dental surgery, and to institute ties in the college. The following were coöpted members the council for the ensuing year:

H. Guy Dain (general practice), G. F. Stebbing (radiology), E. Negus (otolaryngology), A. D. Marston (anæsthetics), George k (ophthalmology), R. V. Bradlaw (dental surgery). L. Carnac tt, subject to the result of the council election (gynæcology obstetrics).

Prof. R. Milnes Walker was re-elected a member of the t of examiners, and the following examiners were elected the ensuing year:

Primary fellowship.—Anatomy: Sir Cecil Wakeley, Prof. H. A. s, Mr. E. C. B. Butler, Mr. James Whillis. Applied physiology pathology: Prof. R. J. S. McDowall, Prof. Geoffrey Hadfield, W. G. Barnard, Prof. Samson Wright.
Diploma of L.R.C.P., M.R.C.S.—Elementary biology: Mr. ld Rushton, D.SC., Mr. J. H. Elgood, Mr. Alan Fisk, Mr. rick Segrove. Anatomy: Prof. Mary Lucas Keene, Mr. A. Moore, Dr. D. V. Davies. Physiology: Professor Dowall, Prof. D. T. Harris. Midwifery: Miss Alice Bloomfield, A. O. Grey, Mr. Norman White, Mr. H. G. Kirwan-Taylor. ology: Dr. J. F. Taylor, Mr. Lennox Broster, Dr. H. W. Mr. R. J. McNeill Love.
Diploma in Public Health.—Preliminary: Dr. Ian McCracken; I, Dr. J. D. Benjafield; Part II, Dr. C. O. S. B. Brooke.
Diploma in Ophthalmic Medicine and Surgery.—Part I, Mr. J. H. art, Mr. G. J. O. Bridgeman; Part II, Mr. T. M. Tyrrell.
Diploma in Psychological Medicine.—Part I, Dr. Denis Brinton.
Diploma in Laryngology and Otology.—Part I, Mr. Charles Keogh, Geoffrey Bateman; Part II, Mr. J. H. Cobb.
Diploma in Medical Radio-Diagnosis.—Part I, Prof. F. L. Hop- d, D.SC.; Part II, Mr. J. L. A. Grout.
Diploma in Medical Radiotherapy.—Part I, Professor Hopwood; t II, Mr. G. F. Stebbing.
Diploma in Anæsthetics.—Dr. W. A. Low, Dr. E. S. Rowbotham.
Diploma in Child Health.—Dr. Wilfrid Sheldon, Dr. A. D. C. Bell.
Diploma in Physical Medicine.—Part I, Dr. Philippe Bauwens, A. M. A. Moore; Part II, Mr. N. St. J. G. D. Buxton, Dr. k Cooksey.
Diploma in Industrial Medicine.—Part I, Dr. Arthur Massey; t II, Dr. William Blood.
Diploma in Tropical Medicine and Hygiene.—Sir Philip Manson- , Dr. Sydney Smith.

Diplomas of fellowship were granted to the following:

I. McA. McArthur, A. S. Bullough, Robert Pettigrew, K. G. Rotter, W. Lipmann Kessel, Philip Shemilt, R. E. Horton, St. J. M. C. Birt, V. Crawford, G. R. Crawshaw, M. H. Kinmonth, F. J. Gillingham, B. Cockett, R. E. Shaw, H. M. Lewis, M. T. Phelis, J. G. Taylor, F. T. Wheeldon, K. W. Wilkinson, B. B. Milstein, D. J. Robertson, S. G. Tuffill, D. P. Choyce, Daniel Anthonisz, D. B. Brown, R. T. Campbell, Maitreyee Chaudhuri, L. P. Clark, R. L. Cooke, J. R. Curtis, E. T. Dick, J. L. Dowling, Marjorie O. Dunster, S. M. Ghosh, N. O. Gibbon, William Girdwood, A. J. P. Graham, R. T. Grime, W. G. Henry, J. P. Heriman, Charles Hollenberg, Boris Lewin, G. M. Lewis, E. T. McCartney, S. T. McCollum, Donald McIntosh, A. M. Mair, H. L. C. Maitland, P. E. Marchand, R. P. Melville, H. D. Moore, E. J. Nangle, S. M. Nawab, G. E. Nevill, J. S. Peters, S. F. Reid, R. B. Scott, R. A. Stephen, H. D'A. Sutherland, R. A. R. Taylor, G. J. Walley.

The following diplomas were granted, jointly with the Royal College of Physicians:

D.A.—D. V. Bateman, O. H. Bekin, C. H. Boyd, W. H. F. Boyd, P. R. Bromage, E. K. Browning, Roger Bryce-Smith, J. E. Bulow, Dennis Carter, A. A. Cilliers, R. B. Clayton, F. E. Clynick, S. W. Coffin, E. R. Coleman, P. B. Connor, C. J. Corcoran, Giovanni Cura, R. M. de Gregory, A. B. Eastwood, I. C. W. English, J. T. Forbes, Andrew Fraser, Eileen McC. Gibson, L. J. Goggin, John Gordon, A. H. Grace, P. W. S. Gray, Harry Grenville, J. H. G. Halliday, J. K. Harper, A. W. Hind, A. C. Holms, H. R. Hudd, Gough Hughes, R. McD. S. Keir, James Lapraik, C. H. Levick, J. K. Lewis, Mary E. Lloyd, R. E. Loder, J. M. MacCormack, R. M. Mackenzie, R. L. McMillan, S. A. Mason, J. G. Matheson, E. T. Morch, P. H. Moore, W. B. Neil, G. S. Ostlere, W. J. Patterson, Joseph Psaila, H. J. Richardson, Hilda Roberts, J. D. Robertson, F. R. Russell, C. F. Scurr, Eugene Thomas, T. C. Thorne, C. E. Tudor, Ambrosine Vaughan, Patricia E. Wallace, Mary Watson, H. L. J. Wilson, G. P. Williams, T. M. Williams, T. N. P. Wilton, E. H. Winterbottom, Luise Wislicki, R. B. Wright.

D.M.R.D.—R. L. T. Hill.

D.C.H.—Sunilkumar Ray.

Commonwealth Travelling Fellowship.—Sir Hugh Cairns, Nuffield professor of surgery in the University of Oxford, has been elected the first Arthur Sims travelling professor. The announcement of the endowment of this chair was first made last November (*Lancet*, 1946, ii, 737), and its title is now to be associated with the name of the donor, Mr. Arthur Sims, a New Zealand industrialist.

Sir Hugh Cairns is a medical graduate of the University of Adelaide, and his main duty as travelling professor will be to visit the principal medical centres of Australia and New Zealand, to deliver lectures, and to take part in research and postgraduate teaching. It is hoped that it will be possible for him to visit the other Dominions during his year of office.

Royal College of Obstetricians and Gynæcologists

At the meeting of the council held on May 31, with Mr. W. Gilliatt, the president, in the chair, it was announced that Field-Marshal Jan Smuts had been elected an honorary fellow. To mark the grant of the royal charter of incorporation the four surviving signatories to the articles of association, whereby the college was founded, were also elected to the honorary fellowship: Prof. J. M. Munro Kerr, Prof. C. G. Lowry, Sir Ewen Maclean, Sir William Fletcher Shaw.

The following were elected to the council to replace those retiring:

Dugald Baird, Alice Bloomfield, G. I. Strachan (*to represent the fellows*); J. A. Stallworthy, A. M. Sutherland, R. James Wotherspoon (to represent the members).

An Australian regional council has been set up to act as a representative committee of the council of the college in discussions and negotiations affecting the practice of obstetrics and gynæcology in Australia. Dr. F. A. Maguire (Sydney) *has been appointed chairman, and* Prof. B. T. Mayes (Sydney) secretary.

The following were admitted to the fellowship:

M. D. Black, J. S. Hovell, Jerusha Jhirad, T. N. MacGregor, Robert Newton, G. D. Shaw, G. S. Smyth, H. S. Waters, Bryan Williams.

The following were admitted to the membership:

Duncan Ballantine, Margaret R. Biggs, W. S. Campbell, J. B. Cochrane, S. J. Cohen, H. V. Corbett, Albert Davis, J. R. Dickinson, Bessie Dodd, Morag Dods, R. C. Gill, Jean L. Hallum, R. F. Lawrence, T. H. Lawton, J. M. McBride, R. A. E. Magee, M. K. O'Driscoll, S. S. F. Pooley, L. J. Quinn, R. B. Salter, P. C. Thomas, Kathleen M. F. Worrall, J. L. Wright.

Indian Medical Service

The Service's annual dinner was held in London on June 12, under the chairmanship of Sir Bennett Hance; the guests were Lieut.-General Sir Alexander Hood, director-general, Army Medical Services, Lieut.-General T. O. Thompson, D.M.S. India, and Mr. William Gilliatt, P.R.C.O.G. Sir Bennett Hance summarised the Service's work for India, and recalled that this was the last dinner which would be held while the Service was still in being. Sir Alexander Hood paid tribute to its contribution to the whole field of tropical medicine; the high standing of the Service was, he said, due not only to the efforts of those officers whose names had become internationally known but to the *steady* work of the ordinary

Royal Appointments

Air Commodore Thomas McClurkin has been appointed honorary physician to the King in place of Air Vice-Marshal K. Biggs who has retired. Air Vice-Marshal Duncan McLaren and Air Commodore F. J. Murphy have been appointed honorary surgeons in place of Air Vice-Marshal A. E. Panter and Air Vice-Marshal T. J. Kelly who have retired.

R.A.M.C. Memorial

On June 12 the Queen was present at a service held in Westminster Abbey in memory of all ranks of the Royal Army Medical Corps who died in the war. Afterwards the Queen, who is colonel-in-chief of the R.A.M.C., laid a wreath below the memorial window, which was rededicated by the Dean of Westminster.

Postponement of Appointed Day

As the appointed day for the start of the National Health Service has been postponed from April 1 to July 5, 1948, local health authorities can be given more time for the preparation of their proposals. The Minister of Health has therefore substituted the following as the last dates for the submission of their proposals instead of the list given in our issue of March 8 (p. 307).

Oct. 31, 1947.—Care of mothers and young children, midwifery, health visiting, home nursing, prevention of illness, care and aftercare, domestic help, duties under Lunacy and Mental Treatment Acts and Mental Deficiency Acts.

Dec. 31.—Health centres.

Tuberculosis Association

The joint annual conference of the association and the Tuberculosis Society of Scotland will be held at the department of zoology, King's Buildings, Edinburgh, from July 16 to 19. The speakers will include Dr. H. A. Pattison (Rehabilitation in the U.S.A.), Mr. T. Holmes Sellors (Assessment of the Results of Thoracoplasty), Dr. H. van den Berg (Control of Results in B.C.G. Trials), Dr. J. G. Scadding (Pneumonias associated with Epidemic Respiratory Infections), Dr. V. Reilly (Pathology of Amyloidosis), Dr. W. M. Borthwick (Genito-urinary Tuberculosis), Prof. V. Monaldi (Endocavitary Aspiration in the Treatment of Pulmonary Tuberculosis), Mr. Norman Dott (Skeletal Traction, Surgical Decompression in the Management of Pott's Paraplegia). Dr. Alexander MacLean and Dr. B. R. Clarke will also open a discussion on the Causes for the Breakdown of Discharged Quiescent Cases.

Births, Marriages, and Deaths

BIRTHS

BARWOOD.—On June 8, at Woking, the wife of Dr. Antony Barwood—a daughter.

COOPER.—On June 7, at Edgware, the wife of Mr. Stanley Cooper, F.R.C.S., Gold Coast—a son.

DUPRÉ.—On May 31, at King's Langley, the wife of Dr. Peter Dupré—a daughter.

FROOME.—On June 10, at Norwich, the wife of Dr. Kenneth Froome—a daughter.

GIMSON.—On June 7, in London, the wife of Dr. Leslie Gimson—a daughter.

HANNAY.—On June 9, at Wimborne, Dorset, the wife of Dr. J. W. Hannay—a son.

KING.—On June 10, in Dublin, Dr. Elizabeth King, wife of Dr. Jeffrey D. King—a daughter.

LEWIS.—On June 5, at Cardiff, the wife of Dr. C. W. D. Lewis—a daughter.

MOORE.—On June 11, at Guildford, the wife of Captain J. T. Moore, R.A.M.C.—a daughter.

WOLFE.—On June 4, at Cardiff, the wife of Mr. H. R. I. Wolfe, F.R.C.S.—a son.

MARRIAGES

BAKER—HOSTE.—On June 7, at Bournemouth, Robert Buckley Baker, M.B., surgeon commander R.N., to Margaret Hoste.

BUCHAN—HENDRY.—On June 14, in London, John Forster Buchan, M.B., to Mary Mabel Hendry.

KENCHINGTON—SWAFFIELD.—On June 11, at Bromsgrove, Noel Scott Kenchington, M.R.C.S., to Barbara M. Swaffield.

PICKERING—BINNIE.—On June 6, in London, Paul Pickering, B.M., to Anne Binnie.

RUTTER—HUNT.—On June 7, at Cardiff, Frank William Eden Rutter, M.R.C.S., to Mary Elizabeth Hunt.

TILSLEY—HOUGHTON.—On June 10, at Sheffield, David Alan Tilsley, M.R.C.S., to Freda Houghton.

DEATHS

FINDLAY.—On June 14, at Farnham, Surrey, Leonard Findlay, M.D., D.SC. Glasg., F.R.C.P., aged 69.

GEPP.—On June 11, at Shrewsbury, Maurice Gepp, L.R.C.P., aged 87.

HATTON.—On June 12, at Claygate, Helen Mary Hatton (née Serjeant), L.R.C.P.E.

HOWELL.—On June 6, at Shaldon, S. Devon, William Boyman Howell, M.D.

MACKINTOSH.—On June 12, in Glasgow, Donald James Mackintosh, C.B., M.V.O., LL.D., M.B. Glasg., D

)GRESS AND PRESENT ASPECTS OF MEDICAL SCIENCE *

Sir LIONEL WHITBY
C.V.O., M.C., M.D. Camb., F.R.C.P., D.P.H.
REGIUS PROFESSOR OF PHYSIC IN THE
UNIVERSITY OF CAMBRIDGE

scipulus est priori posterior dies—each day is the ar of yesterday; and yesterday, the second world was associated with that spectacular progress in in aspects of medicine which always appears as a compensation for lives that are inevitably sacrificed. r what will happen tomorrow, none can tell until has been made. We live in an era when legisla- may alter the whole fabric of the practice of medicine, in due course we shall see how "changes fill the f alteration with divers liquors."

the moment the world is hungry for security— y-to-day economy, in employment, in social services, n the anxieties which illness brings. This may be asic stimulus which lies behind the great movement rds organised research, which urges the lifting of the al standard of medical knowledge, and which calls ıe provision of a medical service capable of making npetent opinion readily available to rich and poor

ch time will be required to create the new order. island is woefully short of medical man and woman r, of equipment, of hospital accommodation, and rsing and domestic staff. These cannot be created ight, and until they are available no State medical ce can operate according to the expectations of the c. When expensive services are free, the use made em is always magnified.

t the country and, to a considerable extent, the ger members of the profession are in the mood to ve this State service; the latter will do their best ake it work. Many returned warriors, weary with ong years of a relatively narrow medical life, are and anxious to rehabilitate themselves for the of providing the country with specialists, the ed men, and the good doctors which the National th Service will need.

SPECIALISM

me there appears to be some danger in the lavish alism which is so freely publicised. Among all the ssion, particularly ex-Servicemen, there is a very ral ambition to be in specialist employment. Shall erhaps, like a Gilbertian navy, be all admirals and r from a galaxy of specialists with none to do the work, the work in the home?

surfeit of specialists leads to unintelligent general cine. The pain in the belly, or any other common tom, tends to present itself not as a problem for iosis but simply as one to be referred for specialist on. Will our general practitioners of the future me no more than sorters of cases? Under Army itions, some evidence of this was apparent. The ngerer, the scrimshanker, was often referred to the ialist as a safety cover, when the old-fashioned nental medical officer—the keen observer, the student uman nature—would have prescribed a couple of ber nines and duty.

multitude of specialists often means that a patient many doctors but not one he can really call his own; one to whom humanity is as important as the expert ion. Let us hope that nationalisation will not inate the oft-ridiculed bedside manner, which in t means a capacity for gaining the confidence of the patient, so that a full and relevant history of background is obtained and cooperation in investigation and treatment is ensured. Should the personal touch go out of medicine, the soul of the profession will pass with it, whatever equipment and facilities are provided.

THE DOCTOR'S LIFE

Much has been said about making the life of the doctor more easy, with shorter hours and longer holidays, more leisure, and financial security for all his working days as well as his old age. This certainly cannot happen overnight, and one wonders how many really desire such things, at the price of independence, or who wish to forgo the stimulus of the gamble of life with the opportunity to make of it what you will. Our profession, all of those who have the instinctive call to be doctors, expect and often glory in the overwork, the perpetual service at all hours if need be; that is all part of the game. The late night call may be a nuisance and something to grouse about, but it brings the thrill always associated with the unknown.

In my view the good doctor—and most are good—will continue to serve the public as before, in spite of being nationalised. It is only the mediocre doctor, the lazy man, the man whose heart is not in his work, who will receive an undue reward for a service in which he can watch the clock.

MEDICAL EDUCATION

We cannot tell whether the profession will continue to attract men of the same calibre and quality—men who have the right background and whose upbringing has inculcated the habit of true service. When a calling is no longer independent and individual, some of its attraction has gone. But it is certain that at least the standard of learning and knowledge will be maintained, and may, by and large, rise, since a long-overdue organisation is being created for postgraduate education in all the university centres. This can be counted a great advantage.

With the expansion of teaching and with the positive development of our university centres will come a proper recognition of the vast contribution which this country has quietly and unobtrusively made, and will continue to make, to the science and art of medicine. Hitherto, in Europe, the German and Austrian centres have been regarded as the mecca to which those in search of advanced medical education should go; whereas Britain, more from diffidence than desert, has been regarded as old-fashioned. It is to be hoped that some of our old-fashioned methods will long continue, and more especially the humane approach.

Even so, we are, once again, woefully short of first-class teachers, and it will take time to create the number required.

RESEARCH

Homines dum docent discunt—men learn as they teach. The great university teaching centres will naturally develop a vigorous policy of research, no longer dependent on the chance financial endowments of enlightened individuals. The university centres will be the focus of each region and should bring into close contact the whole medical population of the region. In theory this should be very beneficial, for the scheme brings into the orbit of research not only the patient with advanced illness but also the clinical material at general-practitioner level representing disease at an earlier phase. Add to this the information supplied by the apparently normal—e.g., in the prophylactic examinations of university students—and there is scope for research covering all aspects of disease, and a medical community willing and interested in supplying all the material. Yet even here caution is necessary. With the perfection of such technical procedures as mass radiography, the value of which was shown by war experience, not only is the abnormal detected but also trivial deviations from normal. Too great an emphasis on such deviations, another danger of specialism (reminding one of the nusiform sac), confuses the boundary between health and disease, and often causes needless anxiety.

---

* ctor Isaac Gilchrist lecture delivered at the University of Aberdeen on May 7.

The war itself proved the quality of our research-workers, but likewise revealed how few we had. This is now recognised by the Government, who are pursuing a positive policy to increase the numbers.

ANTIBIOTICS

The war period showed what can be done by concentrated effort, team-work, and coördinated planning. Of this there can be no better examples than the antibiotics, the chemotherapy of parasitic diseases, and atomic energy.

Penicillin

Fleming's (1929) discovery of penicillin ranks very high in the romances of medicine and clearly shows what part the individual can play in great scientific advances. The story is well known. One day, out of the smoke-laden air of the Borough of Paddington, there descended on to a plate of *Staphylococcus aureus*, which Alexander Fleming was cultivating, a single spore of *Penicillium notatum*. Next day, in the region of the mould, the observer noticed the inhibition of the growth of the staphylococcus. Most of us would have discarded the plate as a reproach to our bacteriological technique. Pasteur said: "Chance favours the trained mind"; and who can doubt that the mind of Fleming was trained and tuned? But more than that, Sachs wrote: "It is not the facts observed but the conclusions drawn from them that determine the progress of science." And Fleming's conclusions in 1929 were in principle all that we nowadays are accustomed to expect from penicillin.

Yet the exploitation of the discovery remained in abeyance for twelve years, and it required the stimulus of war, and the cooperation of chemists, bacteriologists, mycologists, and engineers, and the resources of the commercial world, to give us penicillin in the quantity and in the forms in which we use it today.

Careful study has shown that penicillin consists of at least four substances of varying activity, and of these no more than one has been synthesised. Nature is still a cleverer chemist than man, but man is ingenious at exploiting nature's gift by various routes of administration, in different forms such as pastes, pastilles, and sprays, and in ensuring stability. With the perfection of this work, the culmination of a single observation, a material has been given to us which comes very close to Ehrlich's dream of a non-toxic active antibacterial agent; one of the most powerful remedies against a common mortal infection; a substance which greatly reduced the mortality and morbidity from wound sepsis during the war, and bids fair to succeed with considerable frequency in bacterial endocarditis—a disease which hitherto has defied all methods of control, quite apart from cure.

With the appreciation of the potentialities of penicillin, we have seen the same reaction as when the virtues of sulphanilamide were first recognised. There has been a rapid and frenzied search through a huge range of moulds, bacteria, yeasts, and actinomycetes for an antibiotic which would cover the gaps left by penicillin or which might be superior to it. Numerous moulds have been found to produce antibiotic substances. Some have been dignified by names such as spinulosin from *P. spinulosum*, citrinin from *P. citrinum*, fumigatin from *Aspergillus fumigatus*, and patulin from *P. patulum*—the last enjoying a meteoric rise to fame and an equally rapid fall when a properly controlled experiment showed that it was not the heaven-sent cure for a common cold.
None of these antibiotics has proved of practical
none can attempt to rival penicillin.

Likewise with the antibiotic which Dubos
obtained from autolysed cultures of the soil
B. brevis. This was found to be a mixture of two
peptide substances known as *tyrocidin* and *gr*
Both have proved toxic, and only gramicidin, a
material of crystalline structure, has been su
to limited trial by local application.

Streptomycin

The past few years have seen the discovery
preliminary assays of even another antibiotic
has attracted wide interest, in that it appears to
the door to the treatment of tuberculosis. Strepto
derived from the soil actinomycete *Actinomyce*
has a wide range of activity, apparently filling in
of the gaps which penicillin cannot cover; it is
in vitro against a whole series of gram-negative b
including *Br. abortus*, *Ps. pyocyanea*, proteus, salmo
and *Past. tularense*. But in the human subject tul
is the only disease, so far, in which its value is un
acknowledged. Preliminary trials in competent
suggest that the reaction-rate is fairly high, and
delayed toxic or other sequelæ may occur, whils
capacity of an organism for becoming strepton
resistant is fairly rapidly developed. It seems
that where streptomycin and penicillin overlap ther
be no question of the former replacing the latter.

As to tuberculosis, there can be no doubt of the ac
of streptomycin in vitro and in vivo, but there a
to be very definite limitations. Activity is great
the acute miliary forms of the disease, in which spect
cures, often of limited duration, have been obtain
clinical states hitherto always fatal, including
culous meningitis. But in the common chronic cas
forms of tuberculosis the effect is poor, and even wi
acute disease the arrest or cure has often been a
plished only to leave distressing cerebral sequ
whether due to the disease process or to the ma
itself is not yet certain.

It appears, therefore, that streptomycin does
provide that for which the whole world has long
looking—a simple and easy cure for tuberculosis.
as the action of the sulphonamide drugs is inh
by the presence of pus, the action of streptomy
apparently inhibited by caseation or the barriers
are formed simultaneously.

But at least a hint has been given that tuberc
may one day be controlled. At present the cure o
disease with its protean manifestations and many var
seems unlikely to be accomplished with one single ren
but other substances have been found to have
action, and these too may be capable of further exp
tion. For example, the sulphone group undoub
inhibit the tubercle bacillus in vitro, and though
are far too toxic for general use in the human su
they are available for topical application. There is
the claim that diethyl stilbœstrol has some reta
action on the growth of the tubercle bacillus, a fact
fits well with the long-recognised observation that t
culous women often improve during pregnancy.
then are three lines of approach to the problem of t
culosis, and progress may result from improven
in any or all.

Resistant Micro-organisms

But, despite these great advances in the contr
bacterial diseases, and however great such advances
be in the future, medical science must always prog
It is a remarkable fact that no sooner is the cu
control of one disease accomplished than new prob
appear to arise forthwith. At one time it seemed
gonorrhœa could be almost controlled with the sulp
amides, but nowadays it is recognised that a

portion of cases, many more than hitherto, are lphonamide-resistant." Is this an example of the horism "Make haste to use a new remedy while it is effective," or is it that bacteria are really capable of pid adaptation ? The latter is probably the truth. due course penicillin-resistant staphylococci may come common, whereupon the whole search must gin again. Likewise with streptomycin, to which stance appears to be quickly established.

ANTIMALARIAL DRUGS

Thanks to chemotherapy and efficient methods of munisation, many of the major horrors of war have en largely controlled. In 1939–45 the incidence of phoid and typhus was commendably low; tetanus s a rarity, and the wards were no longer filled with the nk and corruption of gangrene and sepsis. Indeed, matic recovery, no longer retarded by chronic infection, metimes outpaced psychological repair.

Among the most important successes of chemotherapy re the advances made in the prophylaxis and treatment of protozoal diseases. In the Far Eastern campaigns, here casualties from disease were at one time ten nes as numerous as those caused by lethal weapons, e medical services can be considered to have been e most important branch of the general staff. With the rld quinine supplies largely in enemy hands, the rk of our chemists in producing and perfecting e antimalarial drugs—mepacrine, pamaquin, and later 'aludrine'—can be said virtually to have won the rma campaign. The shade of Ehrlich must have joiced at these successes, for chemotherapy may be id to have been born on the day on which Ehrlich's ind connected two simple facts—that methylene-ue stained the malaria parasite, and that methylene-ue was harmless to the human body. Ehrlich tried ethylene-blue for the treatment of malaria; but, ough he obtained a hint of success, the effect was viously inferior to that of quinine. Nevertheless the emical structure of mepacrine is more closely related methylene-blue than to quinine.

SURGERY

Estimates of the efficiency of medical and surgical eatment in the late war are not yet complete, but there n be no doubt that wounded men had at least twice e chance of survival of their predecessors. This is tributable partly to the new methods of immunisation d treatment, and also partly to the high standard of rward surgery, performed by the teams led by young it experienced surgeons who removed devitalised and maged tissue before infection was established and who d their reparative work within a short time of wound-g. None of these measures would have been effective d there not also been a prompt and efficient service aking blood-transfusion available in even the most rward areas. Relatively few died of oligæmic shock, d with this hazard largely controlled there was oppor-nity for the surgeons to do their work and for chemo-erapy to do much to banish the grisly spectre of sepsis.

But even so, and because of the wounded man's reater chance of immediate survival, other dangers nd new knowledge came to light. It was appreciated at so-called neurogenic shock was not a trivial matter, nd that a severely wounded man who had been sanguinated to the point of oligæmic shock or had ffered extensive tissue damage, more especially by ushing, ran a grave risk of remote renal failure.

BLOOD-TRANSFUSION

Under war conditions it was to be expected that great dvances would be made in blood-transfusion. And n fact the civilian and Service blood-bank organisations ere developed so that stored blood and blood substitutes ere freely available in almost any place and in any country, whatever the climate. These facilities have been projected into the regional centres of our coming National Health Service.

Fractionation of Blood

Much progress was made in the perfection of blood substitutes, particularly in the dehydration of human plasma, and the general use of this material should now reduce the mortality from simple hæmorrhage arising from accident or childbirth. But the shape of things to come was notably forecast by the brilliant work of Cohn and his team (1944) on the fractionation of blood. One foresees in the future the deliberate transfusion of a stable selected fraction of blood appropriate to each patient, rather than the mixed bag which whole blood supplies, and which with ordinary methods of preservation may be deficient in the more ephemeral elements. Much has yet to be done to ensure the survival of cellular elements, of which, so far, only the red cells can be preserved for a reasonable time. Much benefit will accrue from the by-products of fractionation work, including the various types of fibrin in the form of film, foam, and plastics. These provide a most physiological method for controlling local hæmorrhage under hitherto difficult conditions.

Rhesus Factors

The wide practice of transfusion, of massive transfusion, and of multiple transfusions has led to a fuller understanding of the virtues and limitations of this form of therapy, and at the same time has revealed unsuspected hazards. By good fortune or otherwise it was discovered early in the war that the high reaction-rate to multiple transfusions and transfusions to pregnant women was due to the immunising potentialities of corpuscular factors. Simultaneously it was appreciated that these so-called rhesus factors were inherited, and that complications might arise under certain conditions of mating which gave a logical explanation of icterus gravis neonatorum and other familial hæmolytic manifestations in the newborn. With the pathology understood, a rational line of treatment for these highly fatal conditions has naturally been developed, which has proved of value in reducing mortality, but not, unfortunately, in influencing the incidence of morbidity in the form of kernicterus.

Intensive study of the rhesus factors has revealed their complexity, the wheels within wheels. Beginning with two factors, rapidly passing to four and then to eight, there still appear to be even more variations within the eight main groups; so that comprehension of the finer technicalities is almost confined to geneticists and specialists.

It appears that the red corpuscle is extremely individual. The more it is studied, the more factors are revealed; and, since all are inherited, the blood of an individual may eventually be found to be as characteristic as his fingerprints. How many new factors will have immunising properties remain to be determined, but no-one nowadays can give multiple transfusions, or can transfuse a woman, with the same simple tests for compatibility which were regarded as a sufficient safeguard before the war.

Much indeed has been learnt about hæmolysins, revealed or latent, complete or incomplete. With the more delicate new tests the pathology of certain obscure anæmias has become more clear, whilst the recognition of "inapparent hæmolysis" has explained the ineffectiveness of transfusion in some blood dyscrasias. With red-cell concentrates the transfusion of anæmic patients whose cardiac musculature is weakened has become a less anxious procedure.

ANÆMIA

In the field of anæmias no really spectacular advance in treatment has been made since Minot's discovery of the virtues of liver in 1926. Throughout the intervening twenty years much study has failed to reveal the exact nature of the liver principle—or principles, for they appear to be many. Crude extracts and proteolysed liver are still acknowledged as containing something which the purified extracts have not. More recently the discovery of the hæmatinic and other actions of folic acid has forged another link in the baffling mystery of blood-production and has opened up a promising field for research and investigation.

NUCLEAR PHYSICS

We live in an epoch-making age, the atomic age, at the crossroads of civilisation. Atomic energy, or nuclear physics, exploited for destructive purposes with incredible rapidity under the stimulus of war, promises immense potentialities for the advancement of medicine—what Chadwick (1947) has called a "safe" development of atomic energy, because the materials which we require can be produced in an apparatus incapable of being used for destructive purposes. With quite small apparatus the transmutation of elements is a commonplace; and radioactive isotopes of almost any element can be obtained. These isotopes, used as so-called "tracers," offer a field for the study of body processes, body metabolism, and organ function, which will take many years to exhaust.

Radioactive Iron.—For example, Fe_{59} and Fe_{55} are used by the body in exactly the same way as ordinary Fe_{56}, but because of their radioactivity their whole course through the body, and their fate, can be traced with measuring instruments. Radioactive iron has been used to determine blood volume in surgical shock, the relative survival in the blood-stream of fresh and stored blood, and the preference of the blood-forming tissues for iron derived from hæmolysed cells to that supplied from without, even when given in large quantities.

Radioactive sodium chloride has been used to determine the rate of distribution by the blood-stream and to measure the lymph volume of particular organs.

Radioactive carbon, nitrogen, and phosphorus have a tremendous application in the study of body metabolism. With radioactive phosphorus, for example, much has already been learnt about the metabolism of the different nucleotides in normal and in tumour cells and the effect of irradiation thereon, the formation of phosphatides in the liver, and the origin of milk phosphorus.

Even preliminary work has shown to what an astounding extent the chemical substances in all tissues are replaced during the life span. It is thought that within the space of ten years every molecule present in the living body of man will have been replaced by a new molecule synthesised within the framework of the living cells. Some radioactive isotopes have been used therapeutically—for example, radioactive phosphorus in the treatment of polycythæmia vera, leukæmia, and certain cancers. Of these only the first has shown any great promise.

Radioactive Iodine.—Certain elements are selectively absorbed by different tissues—for example, calcium and strontium by bone, and iodine by the thyroid gland. Radioactive iodine reaches the thyroid gland within a short time of ingestion; it then gives off rays which generate high-speed electrons, and these affect the neighbouring tissues within a few millimetres—an effect which is ultimately the same as that produced by X rays. But the advantages are that the irradiation is internal and does not therefore affect the overlying skin, whilst the irradiation itself is evenly distributed throughout the whole gland. Theoretically, therefore, radioactive iodine should produce better results than X rays, and this is borne out by clinical reports.

Radioactive cobalt is an excellent substitute for radium, in that it has a steady output of gamma radiation which provides a source of radiation with an intensity five times greater than most of the beam units now available.

RADIOTHERAPY AND CHEMICAL REACTION

Irradiation therapy has long provided the only
tive to surgery, with which it may be combined,
treatment of malignant disease. With new m
providing new and more powerful beams whi
relatively little damage to superficial or overlying
the scope and effectiveness of ray therapy bid
advance, perhaps even to achieve the successes
radiotherapy has accomplished in malignant
of the skin and mucous membranes. Neverthele
as well to appreciate what radiotherapy actually
for therein probably lies the hope of controlling m
disease in the future.

Rays bring about profound biochemical alterati
a cell, particularly the nucleus. Among other t
the synthesis of thymonucleic acid and ribonuclei
is inhibited (Mitchell 1943), and these substance
important constituents of chromosomes in the meta
Inhibition may pass to inanition and so to death. Ir
tion is therefore no more than a crude method of br
about a delicate chemical reaction. Simple ch
changes should be capable of more subtle contro

can exert in the case of prostatic cancer.

NITROGEN MUSTARDS

No-one would have even dreamed that whe
inventiveness of our chemists, stirred by the destr
competition of war, devised mustard-gas, one o
most devastating methods for causing disablemen
death, a new chapter was being opened in the hist
malignant disease. In the 1914–18 war the or
conception of mustard-gas was that hydrochloric
was liberated and so produced the well-known ve
action. Other effects were also noticed, such a
action on the hæmopoietic system, the gastro-inte
tract, and electrolyte balance. Work on musta
was revived with the onset of the second world
Many new and potent chemicals were made. In
was attracted to the cytotoxic effects of both nit
and sulphur mustards, and it was soon apparent
proliferating cells were more susceptible than
cells. This naturally suggested therapeutic possib
for these compounds.

The sulphur mustards, because of their intense che
reactivity and undesirable side-effects, cannot be
clinically. On the other hand, with the nitrogen
tards a whole series of compounds with differing react
can be obtained by varying the grouping attache
the third valence of the nitrogen atom, thus openin
pharmacological possibilities comparable to the ran
sulphonamide variants available for bacterial dise
Threshold doses of nitrogen mustard appear to ha
specific effect on cell nuclei, especially dividing
in a manner comparable to the effect of irradia
Minimal effective doses inhibit mitosis; thoug
mitosis has begun at the time of exposure, the proc
completed normally. Large doses cause nuclear
mentation and chaotic chromatin dispersal. Del
toxic effects occur mainly in the blood-forming org
and lead to lymphopenia, leucopenia, thromboc
penia, and eventually a depression of erythropo
Favourable effects have been obtained in polycythæ
vera and in Hodgkin's disease (Jacobson et al. 1
In the latter, symptoms have been quickly allevia

ilst enlargement of the lymph-glands, spleen, and liver s rapidly declined. Clinical remissions have varied duration from one to eighteen months. The leukæmias d lymphosarcoma do not appear to respond.

So far the nitrogen mustards, like irradiation, have led to cure Hodgkin's disease. But the hint of neficial action is of tremendous import, for literally ndreds of variants await synthesis and evaluation, and may well be that the success which has previously tended the evolution of chemotherapy by chemical teration of a parent compound may also be seen with e β-chloro-ethyl amines.

THE WAY AHEAD

Thus, though progess in the past quinquennium has en outstanding for the breadth of the advancing front, e appear, as always, to be on the threshold of remarkle developments. When one problem is solved or omises to be so, more and more confront us. New fficulties arise as the face of medicine changes and with e changing aspects and manifestations of disease. hy is it, for example, that gastric and duodenal ulceran have so greatly increased; why is it that leukæmia now five times more common than hitherto (Sacks and eman 1947), and likewise many forms of cancer? is not all a matter of improved diagnosis. What is the lation of these patent facts to our increased civilisation, r habits, and our mode of life? It may be that my ccessor in this lectureship, in five years' time, will ve the answer to some of these questions and will mplete the story of the evolution of some of the promisg work upon which I have touched today. *Sic itur astra*—thus do we reach the stars.

NITROGEN MUSTARDS IN HODGKIN'S DISEASE

REPORT ON 21 CASES AND 4 OF OTHER RETICULOSES

M. I. R. ApThomas
M.B. Manc., D.M.R.
CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, MANCHESTER

H. Cullumbine
M.D., M.Sc. Sheff.
DEPARTMENT OF PHARMACOLOGY, VICTORIA UNIVERSITY OF MANCHESTER

The pharmacology of the nitrogenous vesicants, or itrogen mustards, has been summarised by Gilman and hilips (1946). Injected into animals in toxic doses hese compounds provoke an early transient rise in the lood-hæmoglobin content and the red-cell count, ollowed by rapid anæmia and leucopenia (Cameron 942). Loss of weight and diarrhœa occur, and at ecropsy scattered hæmorrhage in the gut is seen. xamination of the bone-marrow reveals that the white ells are more depleted than the red. The leucotoxic ction is mainly on the polymorphs and their precursors; he lymphocyte series is affected, but to a lesser extent Cameron and Rydon 1942).

In many respects the effects produced in animals by hese drugs are similar to those caused by X rays, and t was therefore suggested that the nitrogen mustards night prove useful in the treatment of malignant lisease. Gilman and his associates were the first to use hese compounds clinically. They gave tris β-chloroethyl amine hydrochloride ("tris" form) intravenously o patients with advanced malignant disease. Their esults, together with those of other groups of workers using this compound or methyl-bis β-chloro-ethyl amine hydrochloride ("bis" form), have been summarised by Goodman et al. (1946) and Rhoads (1946). Jacobson et al. (1946) investigated the effect of the bis form on neoplastic diseases of the hæmopoietic system. All these workers found that definite beneficial effects were obtained in Hodgkin's disease, and that some cases of lymphosarcoma, giant follicle lymphoma, and polycythæmia rubra improved. Damage to hæmopoietic tissue did occur, but was for the most part temporary.

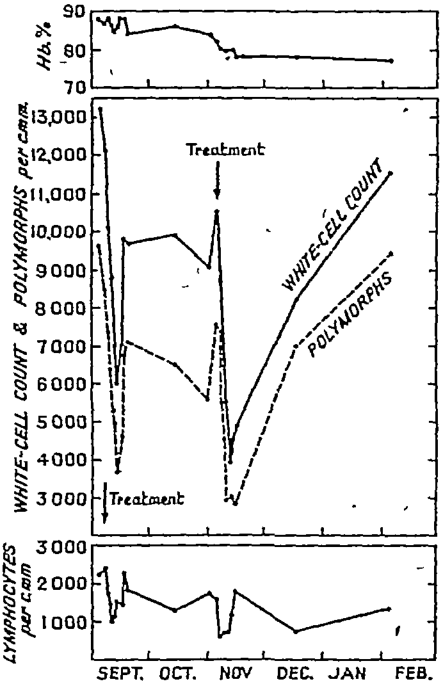

Fig. 1—Typical blood-count responses to two courses of treatment with bis form of nitrogen mustard in Hodgkin's disease.

After the American reports had been received we used the nitrogen mustards in 25 patients: 21 of them had Hodgkin's disease in an advanced stage, some recurrent after radiotherapy; and 4 had other reticuloses. The diagnosis in all cases was confirmed by biopsy.

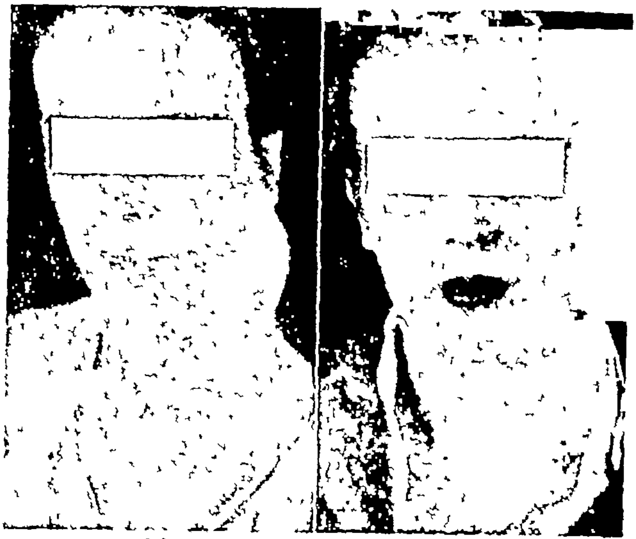
METHOD OF ADMINISTRATION

Because local thrombosis was said to follow more commonly after injection of the tris form of the drug, we gave at first the bis form. The drug was dissolved in 10–20 c.cm. of saline and injected intravenously. The usual dose in the first course of treatment was 0·4 mg./kg. of body-weight. The first patients treated were given an injection of 0·1 mg./kg. of body-weight on four consecutive days; later we gave instead two injections each of 0·2 mg./kg. at 24-hour intervals. This dosage routine was used for both forms of nitrogen mustard, and with the latter technique the period of vomiting was shorter. A few patients were treated by intravenous drip, each dose being dissolved in 500 c.cm. saline, but the method showed no advantage over direct injection in obviating local thrombosis. Courses were repeated after an interval of 6–8 weeks, at a larger dose of 0·3 mg./kg. on each day. Two patients received four daily injections of 0·2 mg./kg., but this dose led to a severe leucopenia and has not been repeated.

TOXIC EFFECTS

Nausea and vomiting occurred at some period in all cases except one. It began during or shortly after injection, varied in severity, and lasted 24–48 hours, continuing longer after the tris than after the bis form. Thrombosis at the site of injection occurred in 6 patients, 2 of whom were receiving the tris form.

The most important toxic effect was leucopenia, most cases showing this within 3–21 days of treatment. In most cases the white-cell count fell to 1500–5200 p c.mm. Neutrophils particularly were reduced. Lymp



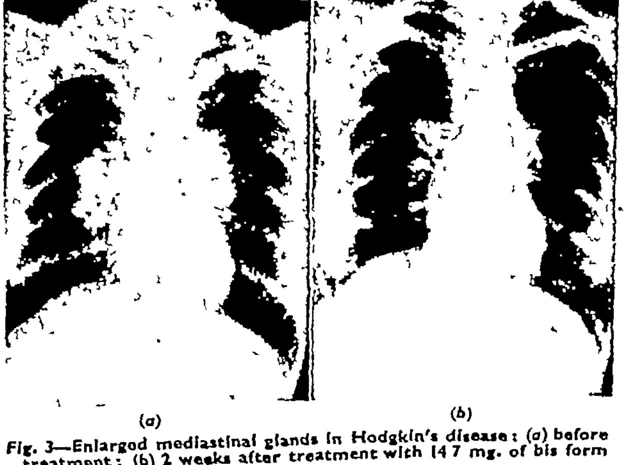
(a) (b)

Fig. 2—Enlarged cervical nodes in Hodgkin's disease: (a) before treatment; (b) 3 weeks after treatment with 22·4 mg. of bis form of nitrogen mustard.

cytes were less affected, and in a few cases increased in number. Exceptional cases included one with a white-cell count of 1300 per c.mm. before treatment; after treatment this was increased. In 5 patients there was a serious diminution in white cells; 2 of them, mentioned above, received double the usual dose of the bis compound, and their white-cell count fell to below 1000 per c.mm. and took about a fortnight to return to normal. The other 3 had the usual dose of the tris form, and in them the very severe leucopenia was accompanied by anæmia, thrombocytopenia, stomatitis, and petechial hæmorrhages. The hæmoglobin fell in one case to 30%, white cells to 200 per c.mm., and platelets to 14,000 per c.mm. The number of platelets fell in all cases treated with the tris form. The bis form did not affect the platelet-count appreciably with the doses used. All patients received iron, and in most cases the hæmoglobin was not diminished by more than 5%. A typical blood response is shown in fig. 1.

RESULTS

The period of observation varied from three to eight months. There was a striking improvement in the patient's general condition, the temperature usually became normal within 24 hours, lassitude disappeared, and weight was gradually gained. Greatly enlarged cervical nodes were reduced in size within a few The response in one patient is seen in fig. 2. radiograms of mediastinal nodes showed a diminution. Fig. 3 shows the effect produced in case a fortnight after the first course of treat a second course led to further improvement in patient. An enlarged spleen was present in 4 pati and in all it became impalpable after treatment.



(a) (b)

Fig. 3—Enlarged mediastinal glands in Hodgkin's disease: (a) before treatment; (b) 2 weeks after treatment with 14·7 mg. of bis form of nitrogen mustard.

Even the most advanced cases showed some be One patient, who had X-ray treatment seven years viously, on admission showed emaciation, pyrexia, cerebrospinal symptoms. After three courses of the form the neurological condition improved, the fever appeared, and she gained $3^1/_2$ st. in weight. In ano patient jaundice cleared temporarily. When he d lymphadenomatous mass was found in the pancreas

All the 21 patients improved after the first course, b many of them required further treatment for recurre of symptoms. Of the 13 patients who had two cours 12 showed improvement after the second course; an of the 4 who had three courses only 2 were improved It is possible, therefore, that the disease responds readi at first but then gradually becomes more resistant t the drug.

The results of treatment with the bis form are sum marised in the table. The 5 patients treated with th tris form have been under observation for three month only; so they are not included. The effect of the tri form on the manifestations of the disease was simila to that of the bis form.

Comparison with Radiotherapy

Comparison of these results with those of deep X-ray therapy at the Holt Radium Institute is of interest The improvement in general condition, nodes, and othe signs was produced more quickly with nitrogen mustard than with X rays but was of shorter duration. In a random batch of 20 cases of generalised Hodgkin's disease undergoing radiotherapy, the mean period of remission after one course of therapy was 9·5 months, whereas most of the cases treated with nitrogen mustard required a second course in about two months; a few had an interval of four to six months between treatments. Vomiting is more likely and more severe after nitrogen mustard than after radiotherapy. There is no skin or mucosal reaction with intravenous nitrogen mustard, but local thrombosis at the injection site has been noted in a few cases. Leucopenia is certain and sometimes severe after nitrogen mustard, whereas after radiotherapy, it occurs only when extensive areas are treated and can be controlled by stopping treatment.

It seems worth while to explore the possibilities of combining radiotherapy with nitrogen-mustard therapy, and this investigation has been started.

Results of Treatment in Other Reticuloses

Four other patients were treated: these included two es of lymphosarcoma, one of which improved; one e of reticulum-celled sarcoma and one of mycosis goides did not show any improvement.

CONCLUSIONS

The nitrogen mustards are useful in the palliative eatment of extensive Hodgkin's disease, the manifestions of which are consistently diminished. The mptoms can still be alleviated by nitrogen mustard cases where radiotherapy has been abandoned.

Leucopenia seems to be the limiting factor, so far as sage is concerned.

The tris form of the drug has shown no better results han has the bis compound. Moreover, diminution of ucocytes and of platelets is more severe after the tris rm.

Radiotherapy is to be preferred as a first treatment Hodgkin's disease; for, though the improvement ith X rays is slower, it is maintained longer and the de-effects are less serious.

We are indebted to the chief superintendent, Chemical fence Experimental Station, Porton, for the supplies of trogen mustard used in this investigation.

GLYCOSURIA IN RECRUITS

INCIDENCE AND CLASSIFICATION

JOYCE A. KEEPING *
M.D. Lond., M.R.C.P.

R. D. LAWRENCE
M.D. Aberd., F.R.C.P.

PHYSICIAN I/C DIABETIC DEPARTMENT, KING'S COLLEGE HOSPITAL, LONDON

DURING the war several papers were published in merica on the incidence and significance of glycosuria recruits to the Armed Forces. Spellberg and Leff (1945), amining 32,644 recruits, found 37 cases of glycosuria, whom 9 (24·3%) had true diabetes mellitus. Blotner nd Hyde (1943a and b), analysing 367 cases of glycosuria iscovered during the examination of 45,650 men, onfirmed diabetes mellitus in 208 (56·6%). Wolman 1946), examining 77,293 men, found 324 cases of elituria, in whom diabetes mellitus was confirmed in 1 (6·5%). The wide variation in these figures is explained part by the fact that many cases of glycosuria had lready been rejected before reaching Spellberg and eff's and Wolman's induction stations, and by the ifference in age-groups. Spellberg and Leff were dealing lmost entirely with men aged 18–35, whereas Blotner nd Hyde included age-groups up to 45 years, and it is ell known that the incidence of diabetes mellitus rises teeply with age. Further, Spellberg and Leff's cases ncluded a relatively high proportion of negroes, in whom iabetes mellitus is less common.

This work led us to survey the cases of glycosuria iscovered by a single urine test at the British medical oards and referred by them to various laboratory entres in London for further investigation. Between 939 and 1944 there were 956 such cases referred, lycosuria *being* confirmed in 782. We have *no idea* of he total number of Service personnel examined, or whether all cases of glycosuria were referred, and so these figures throw no light on the problem of percentage incidence of glycosuria in this sample of the population between the ages of 18 and 45, which are also the ages for life assurance. Nor do we know the sex-distribution, though undoubtedly many more men than women were examined, and of the 956 cases referred for glycosuria only 6 were women. We are concerned here only with the significance and classification of these glycosurias. The numbers are sufficiently large to make the conclusions of the investigation of interest and importance, as it shows that 80% of these glycosurias were non-diabetic. In 8% in our series a single blood-sugar curve gave a doubtful result, and these curves should have been repeated for a conclusive result. But this repetition was often impossible in the circumstances, and a clear answer has to be given at once to the war question: "Is this glycosuria negligible and innocent, or actually or potentially diabetic?"

Urine sugar (%)	0		Trace	1	..	Trace

All the 956 cases referred for glycosuria had urine tests and blood-sugar estimations done, and all but 58 were submitted to a full sugar-tolerance test. The technique used in these examinations varied slightly in the seven different centres. The blood-sugar was estimated on capillary blood in 352 cases, and on venous blood in 535 cases: by the method of Folin and Wu in 632 cases and by MacLean's method in 255 cases. In the remainder the technique used cannot be ascertained. Glucose 50 g. was given for the test in all cases.

DEFINITIONS

Before attempting a classification of this sort it is necessary to define what is meant by the normal and various types of abnormal blood-sugar curves. On this matter there is no absolute consensus of opinion among different workers in different countries, but the standards differ so little that most workers would agree from the results of a single blood-sugar curve whether a patient was diabetic or not. On the other hand, it may be extremely difficult to pronounce him normal, and it is sometimes essential to carry out repeated tests under controlled conditions before coming to a diagnosis.

We therefore had to establish certain definite but somewhat arbitrary figures for this classification. They are standards commonly used in England and at least demonstrate the situation clearly. The classification is based on three concepts:

(1) The normal blood-sugar curve has a fasting level below 120 mg./100 ml., does not rise above 180 mg./100 ml. after the ingestion of glucose, and returns to a normal fasting lev within two hours. During this time there is no sugar in t urine.

Holder of research grant from Messrs. Boots Pure Drug Company.

(2) The normal renal threshold for sugar is 180 mg./100 ml.

(3) After the ingestion of glucose the blood-sugar level in venous blood is 10–50 mg./100 ml. lower than in capillary blood as a result of absorption by the tissues. All figures given in defining these groups are for capillary blood; where venous blood has been used the critical limits have been reduced by 10 mg./100 ml.

CLASSIFICATION

The 782 cases of glycosuria were then divided into four groups arising out of the above definitions.

	No. of cases
(1) *Diabetes Mellitus.*—These show a fasting value which may be normal or raised, a post-glucose rise above 180 mg./100 ml., and a failure to return to 120 mg./100 ml. or lower within two hours	141 (*18%*)
(2) *Renal Glycosuria.*—The blood-sugar curve is normal, but the urine contains sugar, proving a low renal threshold for sugar ..	510 (*65%*)
(3) *Oxyhyperglycæmia or Lag-storage Curve.*—These curves show a normal fasting level, a rapid post-glucose rise above 180 mg./100 ml., but a return to normal fasting value within two hours	108 (*13·8%*)
(4) *Unclassified.*—(*a*) Minor variants: these show either a fasting or a two-hour figure between 120 and 130 mg./100 ml., being normal in other respects	37 (*4·7%*)
(*b*) Major variants: these curves present peculiarities outside the previous three groups	24 (*3·1%*)
	820

The total of 820 is due to the fact that 38 cases (1 diabetic, 20 oxyhyperglycæmic, and 17 slight variants) showed a low renal threshold besides their other abnormality.

As said before, the exact figures adopted for the delimitation of these categories are somewhat arbitrary; but, though some will disagree with them, they gain support from the literature.

Joslin and others (1941), using venous blood, say a normal fasting level should be between 70 and 120 mg./100 ml.; a fasting level between 110 and 130 mg./100 ml. should be regarded as suspicious; and a fasting level above 130 mg./100 ml. "as sufficiently abnormal to warrant a diagnosis of diabetes mellitus"; that the postprandial rise should not be above 170 mg./100 ml., and that it is important that the level should return to normal within two hours.

John (1944), on the other hand, accepts a return to 120 mg./100 ml. or lower in two and a half hours as sufficient to exclude diabetes mellitus.

Blotner (1946) records the results of 479 sugar-tolerance curves in 1383 cases of glycosuria in Service personnel, and classifies 52% as diabetic on criteria which are not entirely clear to us. He appears to define a normal curve as having a fasting blood-sugar level below 130 mg./100 ml. and a peak below 165 mg. in $^1/_2$–1 hour. If the peak is about 165 mg. the patient is potentially diabetic, and if above 170 mg. actually diabetic. In his analysis he seems to pay little attention to the fall of the curve and does not define what the two-hour figure should normally be.

Wolman's (1946) criteria are more precise, and his definition of the normal blood-sugar curve agrees with ours.

Joslin and others (1941) sum up the situation by saying: "Some depend most on the height of curve obtained, others on the length of it, and still others on both. The last attitude is undoubtedly the safest, but even then we regard formal sugar-tolerance tests as often unsatisfactory."

(1) *Diabetes mellitus* was demonstrated in 141 (18%) of the 782 cases. A few of these were declared diabetics on whom the test was carried out for confirmation. The rest were found on routine examination, and most had no inkling of their condition. It would have been interesting to establish the age-distribution of the diabetic cases, but unfortunately this was not noted in 47% of the cases. Of the other half, 54 were over thirty years of age and 20 under thirty, again demonstrating the rapid increase in the incidence of diabetes advancing years.

(2) *Renal glycosurias* present no difficulty and easily recognised by a full blood-sugar curve, accompanying urine tests, or by a single blood- estimation, with urine samples taken immediately and after this test. Some Americans recognise glycosuria only when sugar is passed in the fasting but this seems to us a curious attitude, because with a renal threshold of, say, 130 mg./100 ml. h sugar-free urine when fasting but develop glyco after the ingestion of glucose, though their blood level never rises to the normal average threshol 180 mg./100 ml. Of our 510 patients with renal glyco 203 passed sugar when fasting, 283 only after the inge of glucose, and in 24 this question was not determ Moreover, the renal threshold is not always the sam the rise and fall of the curve, and one commonly that sugar is passed at lower blood-sugar levels d the descent of the curve.

(3) *Oxyhyperglycæmia*, or lag-storage, curves repr the rapid absorption of glucose from the small inte and are the type of curve often seen after ga enterostomy (Lawrence 1936). It is not recognis an entity by the American authorities; but, thoug blood-sugar concentration at $\frac{1}{2}$–1 hour may be as as 250–300 mg./100 ml., the rapid return to no blood-sugar levels within two hours excludes dia mellitus.

(4) *Unclassified* cases present difficulties which n in some cases be cleared by repeated sugar-tole tests. We have subdivided the group into minor major variants, with a feeling that further investig would prove most of the minor variants to be no In most cases one would have liked more inform than was available about their previous diets, fa histories, and general physical condition. Sweeney (first demonstrated the effect of previous diet on tole of sugar; but other factors, such as sepsis, liver dis or thyrotoxicosis, may impair carbohydrate metab either temporarily or permanently. Occasional tech errors cannot be entirely eliminated. In some ca one can postulate as probable causes of the abnorm such things as pylorospasm and trickery; it is kn that some conscripts took adrenaline before their ex nation, to produce glycosuria and raised blood-s levels. In some cases it is impossible to give a dogm opinion on a single curve or, rarely, after repeated bl

TABLE III—MAJOR VARIANTS OF SUGAR LEVELS IN FO RECRUITS

gar curves. It is hoped to consider these abnormal rves in more detail later when more information may available; meanwhile a few examples with possible planations are given. The importance of repeating d following up these abnormal curves cannot be overnphasised.

(a) *Minor Variants.*—Examples are given in tables I d II. In table I both tests demonstrate renal glycosuria; it, whereas the first curve does not return to normal two hours, the repeated curve, ten days later, is normal all respects.

In table II the patient shows renal glycosuria and ain a curve which does not quite return to normal in o hours. The abnormality is slight, but it was known at both parents of the patient had diabetes mellitus, d therefore the curve might in this case represent cipient diabetes. Certainly the sugar-tolerance test this patient should be repeated in 6–12 months.

(b) *Major Variants.*—Four examples are given in ble III. Case 1 shows a normal fasting blood-sugar vel, with a trace of acetone in the urine. After the gestion of glucose the blood-sugar level rises above e normal upper limit of 170 mg./100 ml. and only returns normal in two and a half hours. This type of curve commonly seen as a result of starvation, and the traces acetone in the urine when fasting support this diagnosis. he renal threshold is somewhat raised in this case. ase 2 shows renal glycosuria and delayed absorption sugar such as may result from pyloric obstruction or ne administration of ergotamine. Cases 3 and 4 suggest ickery, most probably by taking adrenaline. Case 4 as tested again next day, when a completely normal urve without glycosuria was found.

SOME OTHER RESULTS

One or two other points have been brought out by his investigation. When samples of venous blood have een used for the blood-sugar estimations, a surprisingly rge number of curves never rise above 120 mg./100 ml. here are only two such "flat curves" where capillary lood was used. Hypoglycæmic levels were seen with onsiderable frequency, but unfortunately we do not now whether these were associated with symptoms of ypoglycæmia or not; presumably they could not have een severe. Blood-sugar estimations on capillary blood howed levels below 70 mg./100 ml. in 9 cases, and on enous blood below 60 mg./100 ml. in 18 cases. Only our of these figures were fasting values, the remainder ccurring $1\frac{1}{2}$–$2\frac{1}{2}$ hours after glucose. One patient, in hom glycosuria was not confirmed, showed extremely ow levels throughout: his fasting blood-sugar level as 57 mg./100 ml.; after the administration of glucose 0 g. it was 61 mg./100 ml. at 45 min., 51 mg./100 ml. t 90 min., and 50 mg./100 ml. at 135 min.

Our incidence of diabetic glycosuria (18%) agrees losely enough with 24·3% of Spellberg and Leff (1945); Volman's (1946) 6·5% is somewhat lower, but all differ idely from 56·6% of Blotner and Hyde (1943b). We nd it difficult both to assess their standards and to gree with their classification. They classify cases as iabetic, or potentially so, if the blood-sugar level at $/_2$–1 hour after the glucose is 165–170 mg./100 ml. and if ugar is found in one or more samples of urine, and we an note no clear emphasis placed on the fall of the curve r on the two-hour figure. Thus it appears that they ould classify many cases as diabetic, either actual or otential, whom we would confidently regard as noniabetic. We have tried to apply their standards to our urves, whereby all our oxyhyperglycæmias and some enal glycosurias become "diabetic," raising the incidence f diabetes mellitus from 18% to 38%, and lowering the enal glycosurias from 65% to 59%, from which it will e seen that even then their percentage incidence of iabetes mellitus still far exceeds ours.

SUMMARY

In routine examination of recruits 782 cases of glycosuria were analysed and divided into four groups according to their blood-sugar curves. Except for 6 women, all the tests were made on men aged 18–45.

The interpretation of the curves often required some latitude and more clinical information than was available, but in classifying this type certain arbitrary limits had to be imposed. Thus, though not entirely satisfactory, it is hoped that this survey is of interest in revealing the relative frequency of the various forms of glycosuria, and particularly in showing that only 18% were diabetic, the remainder being almost entirely due to a low renal threshold.

Our thanks are due to Drs. J. D. Robertson, H. Scott Wilson, R. S. Ralph, D. Stark Murray, T. H. C. Benians, E. Irene Clark, and Martin S. Spink, who kindly placed their results at our disposal.

LABORATORY DIAGNOSIS OF INTESTINAL AMŒBIASIS

K. R. HILL
M.B., B.Sc. Lond.

From the Department of Pathology, Medical School, King's College, and Royal Victoria Infirmary, Newcastle on-Tyne

PATHOLOGISTS in this country when confronted with an occasional investigation, or medical officers arriving in the tropics for the first time, will find in the textbooks only brief accounts of the practical aspects of the laboratory diagnosis of intestinal amœbiasis. It is to supplement such accounts that this article is written.

Much of the information is compiled from notes left behind by Lieut.-Colonels B. G. Maegraith and G. T. L. Archer, R.A.M.C., former assistant directors of pathology, West Africa Command, and from personal experience at a military hospital laboratory, W.A.C., through which passed about 45,000 stools for examination in eighteen months.

Collection of Specimens.—The time-honoured bedpan with fæces fresh from the ward is ideal and, in difficult cases, essential. However, in a laboratory working at high pressure bedpans are impracticable. Empty cigarette tins or, more hygienically, the official fæces containers, consisting of glass bottles fitted with corks carrying a spoon made from sheet tin, are the only methods of coping with large numbers of examinations. Most ambulatory patients are dexterous in supplying a specimen in a cigarette tin, which should be free from antiseptic. In the case of bed patients the selection of the part of the stool for examination is by no means the least important task in reaching a diagnosis and should always be done by the sister.

Acute Intestinal Amœbiasis

NAKED-EYE EXAMINATION OF STOOL

The most frequently observed stool of acute amœbic dysentery is composed of bloodstained semi-solid or liquid fæces in which are scattered small pieces of mucus and small blood-clots. The blood is often dark (occasionally chocolate-coloured) and the mucus tinged dirty brown, quite unlike the white mucus of bacillary dysentery. The reaction is usually acid to litmus, whereas that of bacillary dysentery is alkaline. The stools of amœbic dysentery are always foul-smelling.

MICROSCOPICAL EXAMINATION

Selected Portions of Stool in Saline.—It is essential to examine stools as soon as possible after they have been passed. It is a useful measure to preserve the stool "hot" by placing the containers in an incubator. Iodine-stained preparations from stools containing blood and mucus are unnecessary, and the use of concentration methods does not constitute part of the examination for vegetative amœbæ.

The portion of the stool to be examined should be a selected piece of mucus as free from fæcal matter as possible. If excess of fæcal matter cannot be avoided the mucus should be washed lightly in saline. When blood and mucus are present no other part of the stool need usually be examined.

A loopful of warm physiological saline is placed on a warm slide, a loopful of the selected mucus added and emulsified, and a coverslip pressed down to get the preparation evenly spread on the slide. The best loops to use are made of thick iron wire about 1 mm. in diameter.

As a routine the whole area under the coverslip should be quickly scanned with the $^2/_3$ in. objective. It is important to cut down the light when searching for or examining amœbæ. Suspected parasites should then be examined with the $^1/_6$ in. objective. The identification of amœbæ with the low-power objective always presents some difficulty to the inexperienced, though the introduction of a special stain (see below) has rendered the task easier. Until the observer builds up his experience it will be as well if he conducts his initial examinations by examining every slide with the high-power objective. When an amœba is encountered he can then examine it under the low-power objective and assess its characteristics at this magnification. Only practice will render him proficient in performing the low-power search followed by the detailed high-power differentiation.

The Exudate.—There is no such thing as a typical amœbic exudate. An exudate is said to be "amœbic" only when *Entamœba histolytica* is found. In the acute stages there are many red blood-cells, pus cells, and macrophages, and often necrotic epithelial cells; but, compared with bacillary dysentery, the mucus is relatively non-cellular.

Amœbæ in Saline Preparations.—Care must be taken to distinguish the amœbæ of *E. histolytica* from the non-pathogenic amœbæ of *E. coli, Iodamœba buetschlii, Endolimax nana,* and *Dientamœba fragilis,* as well as from macrophages. *E. histolytica* should never be diagnosed unless one or both of the following criteria are present:

(1) The amœbæ are *progressively motile*—i.e., they move from place to place.

(2) The amœbæ have *ingested red cells; E. histolytica* is unique in this respect, for no other amœbæ found in stools have this property.

Vegetative *E. histolytica* is generally 20–30 µ in diameter, which is also the average size of *E. coli* or a macrophage. *E. nana, I. buetschlii,* and *D. fragilis* are all about 10 µ in diameter and may cause confusion with *E. histolytica minuta,* the smaller variety of *E. histolytica,* which should be considered as pathogenic.

The pseudopodia of *E. histolytica* are finger-like projections which are pushed out "explosively." The whole body of the amœba (both ectoplasm and endoplasm) may flow into the pseudopodium, and it is this which gives the amœba its progression, which is ribbon-like and has been aptly described as like a "slug moving at express speed." This is quite distinct from the motility of *E. coli* and the macrophages. In both the latter the pseudopodia are very blunt and may constitute what looks like a bulging of a large segment of the limiting membrane, and the appearance may suggest itself as the slow movement of a bag of wriggling w Sometimes *E. histolytica* may, for the time bein non-progressive, possibly owing to cooling of the men or to its being caught up by fæcal debris. How if the observer waits he will probably see an expl protrusion of a finger-like pseudopodium in a which prevents confusion with *E. nana* and *I. büet* both of which have well-defined and rather bl pseudopodia which are only sluggishly extended. the other hand, *D. fragilis* does push out finge pseudopodia explosively. The following characteri however, differentiate it from *E. histolytica:*

(1) The pseudopodia may be multiple at any one tim thus take on a star shape or have points and co whereas *E. histolytica* pushes out only one pseudopo at a time.

(2) The pseudopodia become nipped, with the result the ends become spherical, and sometimes they r so for some time; a state which is never seen *E. histolytica.*

(3) At rest *D. fragilis* becomes perfectly circular, wl *E. histolytica* has an irregular amœboid outline.

In *E. histolytica* the ectoplasm is structureless, co tutes from a quarter to a third of the total volume o amœba, and is very different from the finely gra endoplasm. This is also found in *E. nana, I. buets* and *D. fragilis,* but not in *E. coli,* where there is so ectoplasm that it is often difficult to distinguish bet the two components of the cytoplasm. The m phage may have a clear cytoplasm with a large nu but more often there is cytolysis with a ragged cytop surrounding pyknotic nuclei.

In contradistinction to all other amœbæ foun fæces, the nucleus of *E. histolytica* is invisible or is poorly seen in saline preparations, except when endoplasm is flowing into a pseudopodium. If obse the refractile appearance of the nucleus will be that fine thread-like nuclear membrane, studded with chromatin dots with a central single-dot karyos The nuclear membrane and chromatin dots of *E.* are coarse, and the karyosome is eccentric. *E.* has a fine nuclear membrane, very often broke segments, with a single or large karyosome, pl anywhere in the nucleus, sometimes against the nu membrane; *I. buetschlii* has a nuclear membrane chromatin granules, but the karyosome is large vesiculated, often giving the appearance of a "dil pupil"; *D. fragilis* has one or two nuclei with nuclear membranes, multiple chromatin dots inside nucleus but not in the external membrane, and l karyosomes consisting of clusters of granules. macrophage nucleus, unless degenerate, occupies al a quarter of the whole cell; it is not ring-like but s and densely packed with chromatin.

E. histolytica is the only amœba which ingests cells. Macrophages, however, often exhibit inge red cells but also invariably show bacteria, food parti and leucocytes. All amœbæ may show ingested bact and often starch, and *I. buetschlii* has the large c vacuole which indicates the presence of the glyco mass.

Rounded-off Amœbæ.—If the stool has become c or the patient has the clinical condition well na "walking diarrhœa," rounded-off forms may be pre in large numbers. Rounded-off amœbæ are degener with little or no activity, are irregular in shape or rou have sluggish pseudopodia, and are sometimes diffi to differentiate from macrophages. A rounded amœba may be coaxed into activity by heating a m loop (the one used in preparing the microscope specim and holding it to the under surface of the slide as it on the microscope stage. (Ideally a warm stage sho be used.) Often this device is successful, and an explos extrusion of a pseudopodium may give the clue to ar curves. It is hoped to consider these abnormal ves in more detail later when more information may available ; meanwhile a few examples with possible lanations are given. The importance of repeating d following up these abnormal curves cannot be over-phasised.

(a) *Minor Variants.*—Examples are given in tables I d II. In table I both tests demonstrate renal glycosuria ; t, whereas the first curve does not return to normal two hours, the repeated curve, ten days later, is normal all respects.

In table II the patient shows renal glycosuria and ain a curve which does not quite return to normal in o hours. The abnormality is slight, but it was known at both parents of the patient had diabetes mellitus, d therefore the curve might in this case represent ipient diabetes. Certainly the sugar-tolerance test this patient should be repeated in 6–12 months.

(b) *Major Variants.*—Four examples are given in ble III. Case 1 shows a normal fasting blood-sugar el, with a trace of acetone in the urine. After the gestion of glucose the blood-sugar level rises above e normal upper limit of 170 mg./100 ml. and only returns normal in two and a half hours. This type of curve commonly seen as a result of starvation, and the traces acetone in the urine when fasting support this diagnosis. e renal threshold is somewhat raised in this case. se 2 shows renal glycosuria and delayed absorption sugar such as may result from pyloric obstruction or e administration of ergotamine. Cases 3 and 4 suggest ckery, most probably by taking adrenaline. Case 4 s tested again next day, when a completely normal rve without glycosuria was found.

SOME OTHER RESULTS

One or two other points have been brought out by is investigation. When samples of venous blood have en used for the blood-sugar estimations, a surprisingly ge number of curves never rise above 120 mg./100 ml. ere are only two such " flat curves " where capillary ood was used. Hypoglycæmic levels were seen with nsiderable frequency, but unfortunately we do not ow whether these were associated with symptoms of poglycæmia or not ; presumably they could not have en severe. Blood-sugar estimations on capillary blood owed levels below 70 mg./100 ml. in 9 cases, and on nous blood below 60 mg./100 ml. in 18 cases. Only ur of these figures were fasting values, the remainder curring $1^1/_2$–$2^1/_2$ hours after glucose. One patient, in hom glycosuria was not confirmed, showed extremely w levels throughout : his fasting blood-sugar level as 57 mg./100 ml. ; after the administration of glucose g. it was 61 mg./100 ml. at 45 min., 51 mg./100 ml. 90 min., and 50 mg./100 ml. at 135 min.

Our incidence of diabetic glycosuria (18%) agrees osely enough with 24·3% of Spellberg and Leff (1945) ; olman's (1946) 6·5% is somewhat lower, but all differ idely from 56·6% of Blotner and Hyde (1943b). We nd it difficult both to assess their standards and to ree with their classification. They classify cases as abetic, or potentially so, if the blood-sugar level at r 1 hour after the glucose is 165–170 mg./100 ml. and if gar is found in one or more samples of urine, and we n note no clear emphasis placed on the fall of the curve on the two-hour figure. Thus it appears that they ould classify many cases as diabetic, either actual or otential, whom we would confidently regard as non-abetic. We have tried to apply their standards to our rves, whereby all our oxyhyperglycæmias and some nal glycosurias become " diabetic," raising the incidence diabetes mellitus from 18% to 38%, and lowering the nal glycosurias from 65% to 59%, from which it will e seen that even then their percentage incidence of iabetes mellitus still far exceeds ours.

SUMMARY

In routine examination of recruits 782 cases of glycosuria were analysed and divided into four groups according to their blood-sugar curves. Except for 6 women, all the tests were made on men aged 18–45.

The interpretation of the curves often required some latitude and more clinical information than was available, but in classifying this type certain arbitrary limits had to be imposed. Thus, though not entirely satisfactory, it is hoped that this survey is of interest in revealing the relative frequency of the various forms of glycosuria, and particularly in showing that only 18% were diabetic, the remainder being almost entirely due to a low renal threshold.

Our thanks are due to Drs. J. D. Robertson, H. Scott Wilson, R. S. Ralph, D. Stark Murray, T. H. C. Benians, E. Irene Clark, and Martin S. Spink, who kindly placed their results at our disposal.

LABORATORY DIAGNOSIS OF INTESTINAL AMŒBIASIS

K. R. HILL
M.B., B.Sc. Lond.

From the Department of Pathology, Medical School, King's College, and Royal Victoria Infirmary, Newcastle-on-Tyne

PATHOLOGISTS in this country when confronted with an occasional investigation, or medical officers arriving in the tropics for the first time, will find in the textbooks only brief accounts of the practical aspects of the laboratory diagnosis of intestinal amœbiasis. It is to supplement such accounts that this article is written.

Much of the information is compiled from notes left behind by Lieut.-Colonels B. G. Maegraith and G. T. L. Archer, R.A.M.C., former assistant directors of pathology, West Africa Command, and from personal experience at a military hospital laboratory, W.A.C., through which passed about 45,000 stools for examination in eighteen months.

Collection of Specimens.—The time-honoured bedpan with fæces fresh from the ward is ideal and, in difficult cases, essential. However, in a laboratory working at high pressure bedpans are impracticable. Empty cigarette tins or, more hygienically, the official fæces containers, consisting of glass bottles fitted with corks carrying a spoon made from sheet tin, are the only methods of coping with large numbers of examinations. Most ambulatory patients are dexterous in supplying a specimen in a cigarette tin, which should be free from antiseptic. In the case of bed patients the selection of the part of the stool for examination is by no means the least important task in reaching a diagnosis and should always be done by the sister.

Acute Intestinal Amœbiasis

NAKED-EYE EXAMINATION OF STOOL

The most frequently observed stool of acute amœbic dysentery is composed of bloodstained semi-solid or liquid fæces in which are scattered small pieces of mucus and small blood-clots. The blood is often dark (occasionally chocolate-coloured) and the mucus tinged dirty brown, quite unlike the white mucus of bacillary dysentery. The reaction is usually acid to litmus, whereas that of bacillary dysentery is alkaline. The stools of amœbic dysentery are always foul-smelling.

MICROSCOPICAL EXAMINATION

Selected Portions of Stool in Saline.—It is essential to examine stools as soon as possible after they have been passed. It is a useful measure to preserve the stool "hot" by placing the containers in an incubator. Iodine-stained preparations from stools containing blood and mucus are unnecessary, and the use of concentration methods does not constitute part of the examination for vegetative amœbæ.

The portion of the stool to be examined should be a selected piece of mucus as free from fæcal matter as possible. If excess of fæcal matter cannot be avoided the mucus should be washed lightly in saline. When blood and mucus are present no other part of the stool need usually be examined.

A loopful of warm physiological saline is placed on a warm slide, a loopful of the selected mucus added and emulsified, and a coverslip pressed down to get the preparation evenly spread on the slide. The best loops to use are made of thick iron wire about 1 mm. in diameter.

As a routine the whole area under the coverslip should be quickly scanned with the $^2/_3$ in. objective. It is important to cut down the light when searching for or examining amœbæ. Suspected parasites should then be examined with the $^1/_6$ in. objective. The identification of amœbæ with the low-power objective always presents some difficulty to the inexperienced, though the introduction of a special stain (see below) has rendered the task easier. Until the observer builds up his experience it will be as well if he conducts his initial examinations by examining every slide with the high-power objective. When an amœba is encountered he can then examine it under the low-power objective and assess its characteristics at this magnification. Only practice will render him proficient in performing the low-power search followed by the detailed high-power differentiation.

The Exudate.—There is no such thing as a typical amœbic exudate. An exudate is said to be "amœbic" only when *Entamœba histolytica* is found. In the acute stages there are many red blood-cells, pus cells, and macrophages, and often necrotic epithelial cells; but, compared with bacillary dysentery, the mucus is relatively non-cellular.

Amœbæ in Saline Preparations.—Care must be taken to distinguish the amœbæ of *E. histolytica* from the non-pathogenic amœbæ of *E. coli*, *Iodamœba buetschlii*, *Endolimax nana*, and *Dientamœba fragilis*, as well as from macrophages. *E. histolytica* should never be diagnosed unless one or both of the following criteria are present:

(1) The amœbæ are *progressively motile*—i.e., they move from place to place.

(2) The amœbæ have *ingested red cells*; *E. histolytica* is unique in this respect, for no other amœbæ found in stools have this property.

Vegetative *E. histolytica* is generally 20–30 μ in diameter, which is also the average size of *E. coli* or a macrophage. *E. nana*, *I. buetschlii*, and *D. fragilis* are all about 10 μ in diameter and may cause confusion with *E. histolytica minuta*, the smaller variety of *E. histolytica*, which should be considered as pathogenic.

The pseudopodia of *E. histolytica* are finger-like projections which are pushed out "explosively." The whole body of the amœba (both ectoplasm and endoplasm) may flow into the pseudopodium, and it is this which gives the amœba its progression, which is ribbon-like and has been aptly described as like a "slug moving at express speed." This is quite distinct from the motility of *E. coli* and the macrophages. In both the latter the pseudopodia are very blunt and may constitute what looks like a bulging of a large segment of the limiting membrane, and the appearance may suggest
itself as the slow movement of a bag of wriggling
Sometimes *E. histolytica* may, for the time bei
non-progressive, possibly owing to cooling of the
men or to its being caught up by fæcal debris. Ho
if the observer waits he will probably see an ex
protrusion of a finger-like pseudopodium in a
which prevents confusion with *E. nana* and *I. b*

has a fine nuclear membrane, very often brok
segments, with a single or large karyosome,
anywhere in the nucleus, sometimes against the n
membrane; *I. buetschlii* has a nuclear membran
chromatin granules, but the karyosome is larg
vesiculated, often giving the appearance of a "d
pupil"; *D. fragilis* has one or two nuclei wit
nuclear membranes, multiple chromatin dots insid
nucleus but not in the external membrane, and
karyosomes consisting of clusters of granules.
macrophage nucleus, unless degenerate, occupies
a quarter of the whole cell; it is not ring-like but
and densely packed with chromatin.

E. histolytica is the only amœba which ingest
cells. Macrophages, however, often exhibit ing
red cells but also invariably show bacteria, food par
and leucocytes. All amœbæ may show ingested ba
and often starch, and *I. buetschlii* has the large
vacuole which indicates the presence of the gly
mass.

Rounded-off Amœbæ.—If the stool has become
or the patient has the clinical condition well n
"walking diarrhœa," rounded-off forms may be pr
in large numbers. Rounded-off amœbæ are degene
with little or no activity, are irregular in shape or ro
have sluggish pseudopodia, and are sometimes dif
to differentiate from macrophages. A rounde
amœba may be coaxed into activity by heating a
loop (the one used in preparing the microscope speci
and holding it to the under surface of the slide as i
on the microscope stage. (Ideally a warm stage sh
be used.) Often this device is successful, and an expl
extrusion of a pseudopodium may give the clue to

entity of an *E. histolytica*. If this is unsuccessful, and active amœbæ have not been found in other examina ons of the same stool, these facts are reported as: Rounded-off amœbæ seen—identity unknown, please peat." "Presumptive *E. histolytica*" should never reported, for it is impossible to be exact about the entity of amœbæ in their rounded-off state. Such nœbæ disintegrate and die; they do *not* form cysts.

ADJUNCTS TO DIAGNOSIS

Aqueous Smears (Hakansson [1]).—An aqueous prepara on similar to the saline one is made. All vegetative rms of amœbæ are destroyed within 5–15 min., but e modes of destruction afford a good differentiation etween *E. histolytica* and *D. fragilis*. *D. fragilis* in queous smears has an explosive extrusion of its endo lasm within about 15 min., immediately followed by sealing at the point of extrusion by the ectoplasm, aving a faultless transparent sphere. *E. histolytica* nd *E. coli* rupture explosively, but there is never mplete emptying of the endoplasm; nor is there storation of the ectoplasmic shell. *E. nana* and *buetschlii, on the other hand, distend to a maximum,* hen they burst and crumble.

Wet Film Stain (Beemer [2]).—This consists of two lutions:

Solution A

Brilliant cresyl blue	0·2 g.
Sod. citrate	1·1 g.
Sod. chloride	0·55 g.
Hyd. perchlor. (sat. soln.)	0·1 c.cm.
Water	100 c.cm.

Solution B

Eosin	1 g.
Water	100 c.cm.

his stain has been used in my laboratory with success, pecially in the training of medical officers and labora ry technicians. A loopful of solution A and a loopful solution B are mixed on a slide, the selected piece of ucus is emulsified in the stain, and a coverslip is applied. ctive amœbæ take up the particles of cresyl blue, with he result that they are easily picked out as blue-green bjects under the low-power objective. Motility seems o be unimpaired by the stain, and amœbæ have been ound active under the coverslip seven hours after the reparation has been made and left on the bench in a Vest African laboratory.

Chronic Intestinal Amœbiasis

Under this heading are included cases of chronic mœbic dysentery and of the complications of amœbiasis, uch as liver abscess, convalescent cases, and carriers ho may be handlers of food.

NAKED-EYE EXAMINATION OF STOOL

More often than not the stool in these cases will be ormed and of normal appearance. However, super cial shreds of mucus and blood may be detected on lose examination. If the stool is loose it is often f the "pea-soup" variety or light chocolate-coloured. nvariably it has a *foul smell.*

MICROSCOPICAL EXAMINATION

The same procedure is used as for acute amœbic ysentery, with the addition of an iodine preparation nade with the following solution:

Iodine	1 g.
Pot. iodide	2 g.
Water	100 c.cm.

Often specimens from this type of case contain no lood and no mucus, and in such a case several examinations of different parts of the outside of the fæces are made. Time is better spent on multiple examinations of a specimen of fæces than on concentration methods for cysts. Further, in cases of suspected amœbic dysentery it is imperative to examine several specimens, and as a routine it is suggested that specimens be examined every second or third day for ten days. For convalescent cases, after a full course of treatment lasting 3–6 weeks, stools should be examined daily for the week before discharge, then once monthly for three months, and then once every six months as conditions indicate.

The Exudate.—The commonest findings are scanty red cells and a few leucocytes, but the appearances may vary from no exudate at all to those described under acute intestinal amœbiasis. The presence or absence of Charcot-Leyden crystals is not considered significant.

Cysts in Saline Preparations.—Cysts are very easily picked up with the $^2/_3$ in. objective. In general, cysts of *E. histolytica* are perfectly round but they vary in size, measuring anything from 5–20 μ in diameter. Cysts of *E. coli* are usually bigger, 10–30 μ in diameter and are round or oval, but sometimes one side alone is flattened. As a rule *E. nana* and *I. buetschlii* are irregular and smaller, with a diameter of 5–15 μ.

One characteristic feature of *E. histolytica* cysts in the unstained preparation is that the nuclei are nearly always invisible whereas those of *E. coli* and *I. buetschlii* are easily seen. The nuclear visibility of *E. nana* is poor. The cytoplasm of *E. histolytica* is clear and homogeneous, and that of *E. coli, E. nana,* and *I. buetschlii* coarsely granular, but *I. buetschlii* has a large highly refractile vacuole denoting the site of the glycogen mass.

About 90% of *E. histolytica* cysts show highly refractile chromidial bars which are usually broad and blunt. About 10% of *E. coli* exhibit chromidial bars, which are generally acicular. However, I have seen acicular chromidial bars in *E. histolytica* and blunt bars in *E. coli. E. nana* and *I. buetschlii* have no chromidial bars, but *E. nana* occasionally shows long filamentous rods.

Besides the above cysts there may be present in the saline preparation many cyst-like structures, such as *Blastocystis hominis,* of vegetable origin. Some forms of blastocystis will resemble protozoan cysts so closely that even the expert may be in doubt about their identity. Such cases are usually those in which the peripheral granules have been lost, or displaced into the centre, with the result that they resemble chromatoid bodies. Further, the presence of *Blastocystis hominis* in large numbers, even if recognised, increases the difficulties of the search for cysts of *E. histolytica,* particularly if these are scanty. Fortunately, with the use of the aqueous preparation, the blastocystis can be eliminated, as it rapidly distends, loses its refractability, and appears dull and dead compared with the glistening protozoan cysts.

Cystic forms of *D. fragilis* are never found, but the vegetative form in the resting phase in saline has a perfectly circular outline and may resemble a cyst of *E. histolytica.* However, such forms disintegrate very quickly in the fæces; hence, if the specimen is left 15–30 min., *D. fragilis* will have disappeared, leaving the true cysts behind if they are present.

Cysts of the ciliate *Balantidium coli* are very large, being about 50 μ in diameter, and textbook illustrations so faithfully reproduce the microscopical picture of such cysts and of the cysts and ova of other parasites, with their distinctive internal structures, that there should be no likelihood of confusion with cysts of *E. histolytica.*

Oil globules in the fæces—e.g., liquid paraffin—are easily identified by their multiplicity, their variable size, *their very high refractability,* and their failure to stain with aqueous iodine.

Cysts in Iodine Preparations.—The iodine preparation can be made directly from the fæces, as for the saline preparation, or iodine solution can be run under the coverslip of the saline preparation. This latter method is especially useful if a doubtful cyst is in the field of the microscope and its exact identity is to be established. This entails dexterity (which can be acquired) and luck, for the application of the iodine usually sets the field moving.

---

[1] Hakansson, E. G. *Amer. J. trop. Med.* 1942, 22, 325.
[2] Beemer, A. M. A. Army Pathology Laboratory Service: Current Notes, 1945, no. 14, p. 3.

The nuclear characteristics are similar to those described for the respective vegetative forms but are more clearly outlined. *E. nana* and *I. buetschlii* very often show a large mass of chromatin which tends to obscure the whole nucleus. *E. histolytica* has 1–4 nuclei, *E. coli* 1–8, *E. nana* 1–4, and *I. buetschlii* 1 (sometimes 2), the exact number being ascertained by focusing up and down on the slide.

The cytoplasm of *E. histolytica* when stained with iodine is seen to be finely granular, whereas that of the three other cysts is coarsely granular (most marked in *E. coli*).

The iodine stain tends to bring out the glycogen mass, when present, in all four cysts, but it should be noted that a glycogen mass may not be present, and chromidial bars do not stain with iodine.

The glycogen mass of *E. histolytica* is always a faint brown indefinite patch tending to disappear as the cyst attains maturity—i.e., 4 nuclei. The glycogen mass in cysts of *E. coli* is large and deeply stained, tending to push the nucleus to the edge and so flatten it. It reaches its maximum at the 2-nuclei stage and has disappeared at the 4-nuclei stage. *E. nana* shows a small poorly stained glycogen mass at the 2-nuclei stage, but *I. buetschlii* always presents a large, clearly outlined, and almost black mass—hence its generic name.

The diagnosis of *E. histolytica* is often not easy and in general can only be made by carefully deliberating and summating all positive findings. For example, there is often great difficulty in differentiation between *E. coli* and *E. histolytica* up to the 4-nuclei stages:

(1) *Cysts with 1 nucleus and central karyosome:* though the karyosome of *E. coli* is said to be eccentric, it is obvious that, if the cyst is turned so that the karyosome is viewed in direct line with the centre of the nucleus, the karyosome will appear to take a central position and will resemble that of *E. histolytica*. Differentiation, however, would be made on the visibility of nuclear detail and the presence of chromidial bars in the saline preparation, and on the cytoplasmic granularity and nuclear membrane structure, as previously outlined in the iodine preparation. The glycogen mass at this stage is indeterminate.

(2) *Cysts with 2 nuclei*, showing very often a large glycogen mass pressing and flattening the nuclei to the sides, are characteristic of *E. coli*. If the glycogen mass is absent (as it may be), the diagnosis hinges on the other differential findings described above.

(3) *Cysts with 4 nuclei* sometimes show one, two, or three centrally placed karyosomes and the remainder eccentric. However, the presence of only one eccentrically placed karyosome is almost peculiar to *E. coli*. The karyosome of *E. histolytica* is always central and never eccentric; that of *E. coli* is eccentric but may appear to be central.

In the above description the cysts of *Giardia lamblia* have not been included; but, since iodine preparations always reproduce most faithfully the illustrations in textbooks, there should be no difficulty in identification.

ADJUNCTS TO DIAGNOSIS

Provocative Emetine.—The following procedure is very efficacious and should be more often used in ambulatory cases:

> The night before the examination, two to three hours after the last meal, the patient is given emetine hydrochloride gr. 1 intramuscularly. Next morning a saline purgative—e.g., mag. sulph. $^1/_2$ oz.—is administered, and the first, second, and third stools are examined for amœbæ.

As an alternative to emetine hydrochloride, emetin muth iodide (E.B.I.) gr. 3 may be given by mouth. drug is likely to cause vomiting, which, however, prevented by the giving of phenobarbitone gr. $^1/_2$ a before the administration of the E.B.I.

Sigmoidoscopy.—This procedure, though necess admission to hospital for two or three days, well the trouble expended. The following is a modifi of the procedure originally suggested by D'Anton

> The evening before the test, provocative emetine (or E.B.I. gr. 3) is given at 8 P.M. and is followed by sulph. $^1/_2$ oz. at 11–12 P.M. Next morning at 6 A.M. (o a half hours before sigmoidoscopy) a litre of warm p logical saline is given as an enema. This is returne another litre is given, a specimen from the last portion enema being retained on evacuation for examination. and enema specimen are examined by direct-smear pr tions. Sigmoidoscopy is then performed, suspicious of the mucosa are swabbed, and smears are made for examination from the swabs.

Summary

The laboratory diagnosis of acute amœbic dys is described.

In saline preparations the salient characteristi *E. histolytica* are progressive motility and ingesti red cells.

For the occasional difficult differentiation be *E. histolytica* and *D. fragilis* aqueous preparatio recommended, and for ease in identification an teaching purposes a method of wet staining is desc

Rounded-off forms of vegetative amœbæ cann identified with any exactitude. They should a be reported as: "Rounded-off amœbæ seen—id unknown—please repeat."

The diagnosis of chronic amœbic dysentery (incl carriers and convalescents) is made with saline iodine preparations for the identification of cysts.

Multiple examinations of several specimens several days are considered to give better results concentration methods.

As adjuncts to diagnosis the use of provocative em and sigmoidoscopy are described.

I wish to thank Dr. R. Mowbray for his advice in w this paper, and also Lieut.-Colonels Maegraith and A though the opinions here expressed are the author's own

INTRAPLEURAL HÆMORRHAGE FOLLOWING ARTIFICIAL-PNEUMOTHOR REFILLS

w.o. = wash-out with saline; asp. = aspiration; bl.st. = bloodstained.

es and females. The technique is one commonly d, in which a Morland needle, diameter 2 mm., ected to an appropriate *pneumothorax* apparatus, hrust through an intercostal space near the upper gin of a rib, usually without previous anæsthetisan, save at the induction and the two succeeding ls. This method is practically painless in most es if a sharp needle is used.

During the past three years 6 cases of bleeding (5 in men, a woman) have been recognised at this hospital, an dence of 1 in 2500. In all the cases but one there s a free pleural space without adhesions; in one pleura was adherent to the mediastinum. Another e, in a male, was noted by one of us (A. K. M.) in about 0 refills in six years. A further case, also in a male, s admitted from a tuberculosis clinic, but no estimate sible of the incidence there; this case is not included the present series.

Diagnosis.—In making a diagnosis the presence of in during a refill has been helpful. In 3 cases the tient noted or recalled that the refill was definitely inful, one of these cases being the only one in which cal anæsthetic was used. In 2 of these cases the in diminished directly the needle was withdrawn, and 1 case disappeared immediately only to recur thirty rs later.

In all cases pain was experienced later the same day, ve in one case where it did not develop within thirty urs. The pain is similar to that experienced at the et of a pleural effusion—i.e., a dull ache, never very vere, and quite different from the pain experienced at ill. Malaise, such as is seen with the onset of a ural effusion, is usually absent, and this proved very pful in making a clinical diagnosis.

In 4 cases there was a rise of temperature before pirations were carried out. In 1 case this took place e same evening, but in the remaining cases it took ace some time during the next three days. In those ses that were aspirated immediately there was no rise f temperature, and it seems probable that this was revented by early aspiration. A brisk rise of temperaure usually followed the aspirations but soon settled.

Treatment.—In these cases treatment is important. n all our cases aspirations were carried out immediately e hæmothorax was diagnosed. When aspirations were performed, the pleural space was washed out with saline, and this was continued until the return fluid was clear. In some cases difficulty was experienced in carrying out the first aspiration owing to flakes of fibrin covering the end of the cannula when suction was applied. After the first aspiration the patient was screened daily, and if any fluid reappeared this was aspirated and, if blood was present, was washed out as described above. This may have to be done several times, as bleeding may continue.

In 3 cases the condition was recognised within twenty-four hours, in 1 case after forty-eight hours, and in another case after seventy-two hours. In the remaining 2 cases it was not discovered until the eighth and twelfth days, after pleural exploration.

The accompanying table shows that in 4 cases aspiration was necessary only once, whereas in the remaining 3 cases up to five aspirations with saline wash-outs were necessary before the pleural space was free from bloodstained fluid.

Results.—A follow-up of these cases shows that no artificial pneumothorax was lost in those cases that were aspirated within forty-eight hours. There was partial obliteration in 1 case, but the patient still had an adequate collapse on discharge eight months later.

Where the aspirations were delayed more than forty-eight hours, obliteration of the pleural space took place in all cases, in 2 of which the pneumothorax was lost completely. In the remaining case there were definite radiological appearances of an incipient obliterative process at the base, but a follow-up of this case showed that the collapse was still satisfactory and controlling the tuberculous lesion three months later.

Our most recent case with this complication illustrates the more common points.

A man, aged 42, had a refill at 10 A.M. The refill was definitely painful the whole time the needle was in the chest, but the pain was not bad enough to warrant the removal of the needle. After he had risen from the couch, the pain, though less, persisted.

He was seen at 12.30 P.M. still complaining of diffuse pain in the axilla round the site of the refill. As he still had pain at 6 P.M. he was screened, and a small effusion was seen in the costophrenic angle. The same night the temperature reached 99°F.

Next morning he was again screened, and the fluid was found to have increased slightly. The same day 1 oz. of blood was aspirated and the space washed out with saline. After this the pleural space remained dry and the patient had no further discomfort.

At thoracoscopy later a small thread-like artery was seen branching about the site of the refills, and a larger vein crossed this area. There seemed ample reason to suppose that a hæmorrhage might arise from puncture of one of these vessels.

DISCUSSION

The presence of the blood in the interpleural space is not likely to be due to the damage of an intercostal vessel, as the needle is purposely inserted near the upper margin of a rib, and in pleural hæmorrhage it is probably due to a vessel subpleurally placed. On many occasions there is bleeding from a small surface vessel after an artificial-pneumothorax needle has been withdrawn, and there is every reason to believe that the same might happen from a surface vessel on the parietal pleura, which is very much more vascular than the skin.

The signs and symptoms produced by this complication may be minimal and would probably only be noticed where the patient is under direct observation, as in a sanatorium. Even then they may be so slight that it might be considered a refill "reaction," and no further investigation might be carried out.

Pain on the insertion of the artificial-pneumothorax needle should arouse suspicion. Waterston (1934) states that puncture of an artery produces severe pain, which tends to radiate along the course of the artery; such pain is usually attributed to injury to the intercostal nerve. The importance of this syndrome lies in the fact that obliteration of the pneumothorax space usually follows, unless the blood is aspirated without delay. Indeed the injection of blood into the pleural space has been recommended as a method of securing symphysis of the pleural layers. We are of the opinion that, once there has been any intrapleural bleeding, fibrin is deposited on the pleural surface, with the resulting risk of losing the pneumothorax through an obliterative pleurisy.

SUMMARY

In 15,000 refills there were 6 cases of intrapleural hæmorrhage. A 7th case in 3600 refills was seen elsewhere.

Pain was present in all the cases.

In 4 cases the pleural space became obliterated.

To avoid obliteration of the space early aspirations and wash-outs are essential.

Bleeding may continue for several days.

Waterston, D. (1934) *Brit. med. J.* ii, 1087.

"... There are shortages of food, clothing, and housing.... But our standard of life does not consist in these things alone. Security of employment; higher average earnings, longer holidays, and holidays with pay; the schools, technical colleges, and universities fuller than ever before; a social insurance scheme coming into operation stage by stage; a State medical service available to all about to be set up, and a nation which the statistics show to be healthier than ever before—these are not the indications of a collapsed standard of living, although I agree they are not all things of which the middle classes are always able or always inclined to take full advantage. Our aim ... is to make the State educational system and the State medical service better than anything that can be obtained privately.... They must be made so good that the middle classes will use them in preference to private services for which they have to pay over again." —Sir HARTLEY SHAWCROSS, the Attorney-General, speaking at Croydon on June 20 (*Times*, June 21).

es and females. The technique is one commonly d, in which a Morland needle, diameter 2 mm., nected to an appropriate pneumothorax apparatus, hrust through an intercostal space near the upper gin of a rib, usually without previous anæsthetisa- t, save at the induction and the two succeeding lls. This method is practically painless in most s if a sharp needle is used.

uring the past three years 6 cases of bleeding (5 in men, a woman) have been recognised at this hospital, an idence of 1 in 2500. In all the cases but one there s a free pleural space without adhesions; in one pleura was adherent to the mediastinum. Another e, in a male, was noted by one of us (A. K. M.) in about 0 refills in six years. A further case, also in a male, admitted from a tuberculosis clinic, but no estimate ossible of the incidence there; this case is not included the present series.

iagnosis.—In making a diagnosis the presence of n during a refill has been helpful. In 3 cases the ient noted or recalled that the refill was definitely inful, one of these cases being the only one in which ocal anæsthetic was used. In 2 of these cases the n diminished directly the needle was withdrawn, and 1 case disappeared immediately only to recur thirty urs later.

n all cases pain was experienced later the same day, e in one case where it did not develop within thirty urs. The pain is similar to that experienced at the et of a pleural effusion—i.e., a dull ache, never very ere, and quite different from the pain experienced at ll. Malaise, such as is seen with the onset of a ural effusion, is usually absent, and this proved very lpful in making a clinical diagnosis.

n 4 cases there was a rise of temperature before pirations were carried out. In 1 case this took place e same evening, but in the remaining cases it took ce some time during the next three days. In those es that were aspirated immediately there was no rise temperature, and it seems probable that this was evented by early aspiration. A brisk rise of temperare usually followed the aspirations but soon settled.

reatment.—In these cases treatment is important. all our cases aspirations were carried out immediately e hæmothorax was diagnosed. When aspirations were performed, the pleural space was washed out with saline, and this was continued until the return fluid was clear. In some cases difficulty was experienced in carrying out the first aspiration owing to flakes of fibrin covering the end of the cannula when suction was applied. After the first aspiration the patient was screened daily, and if any fluid reappeared this was aspirated and, if blood was present, was washed out as described above. This may have to be done several times, as bleeding may continue.

In 3 cases the condition was recognised within twenty-four hours, in 1 case after forty-eight hours, and in another case after seventy-two hours. In the remaining 2 cases it was not discovered until the eighth and twelfth days, after pleural exploration.

The accompanying table shows that in 4 cases aspiration was necessary only once, whereas in the remaining 3 cases up to five aspirations with saline wash-outs were necessary before the pleural space was free from bloodstained fluid.

Results.—A follow-up of these cases shows that no artificial pneumothorax was lost in those cases that were aspirated within forty-eight hours. There was partial obliteration in 1 case, but the patient still had an adequate collapse on discharge eight months later.

Where the aspirations were delayed more than forty-eight hours, obliteration of the pleural space took place in all cases, in 2 of which the pneumothorax was lost completely. In the remaining case there were definite radiological appearances of an incipient obliterative process at the base, but a follow-up of this case showed that the collapse was still satisfactory and controlling the tuberculous lesion three months later.

Our most recent case with this complication illustrates the more common points.

A man, aged 42, had a refill at 10 A.M. The refill was definitely painful the whole time the needle was in the chest, but the pain was not bad enough to warrant the removal of the needle. After he had risen from the couch, the pain, though less, persisted.

He was seen at 12.30 P.M. still complaining of diffuse pain in the axilla round the site of the refill. As he still had pain at 6 P.M. he was screened, and a small effusion was seen in the costophrenic angle. The same night the temperature reached 99°F.

ology cast some doubt on this assumption; so mice inoculated. The mice died in less than twenty-four and at necropsy their blood and spleens showed very umbers of organisms with the bipolar staining charac- o of *Past. septica.* Cultures from them gave rise to forms he same morphology as that noted on primary isolation. organisms were not acid-fast and no spores were seen. ty was absent when cultures grown at 37°C and 22°C ested.

ural and Other Characteristics.—Colonies after eighteen growth on blood-agar were shining, confluent, greyish- , and translucent. They were of creamy consistence asily emulsified. There was no hæmolysis and no ing of the blood-agar. Growth was enhanced by the on of blood or serum to the medium. On both, a good turbidity developed in twenty-four hours; it was much ed after a week's incubation and gave rise to a heavy deposit which was easily emulsified. There was a growth on MacConkey plates in twenty-four hours.

following sugars, of a large number tested, were ated (acid only): galactose, glucose, mannitol, sorbitol, ylose. Slight acidity occurred in arabinose. There was teration of litmus milk, and the methyl-red test was ive. Indole was produced. There was reduction of lene-blue.

organism was killed by heat in 5 min. at 56°C, but ed exposure to 0·5% phenol for 60 min. at room tem- ure. Its coefficient of resistance to penicillin, measured e broth method and with standard (Oxford) staphylo- s as control, was 128.

ology.—An agglutinating serum giving a titre of 1/640 repared by intravenous inoculation of a rabbit with d doses of an emulsion of the organism A.W. killed by g at 56°C for 30 min.

glutination tests were set up against four strains of *septica* obtained from the National Collection of Type res, one of each of Cornelius (1929) serological types included. Of these, no. 1737 (N.C.T.C.—C type III) gglutinated to a titre of 1/640, whereas nos. 948 (N.C.T.C. pe II) and 1875 (N.C.T.C.—C type IV) gave a titre of

sorption tests were carried out with emulsions of strains and 1737 (Cornelius type III) and the antiserum A.W. absorbed sera were used in agglutination tests against ons of A.W. and 1737, and gave the following results:

	Serum A.W.		
ganism	*Unabsorbed*	*Absorbed A.W.*	*Absorbed* 1737
A.W. ..	1/640	—	1/80
1737 ..	1/640	—	—

is evident from these tests that the strains A.W. and (Cornelius type III) are closely allied but not serologically ical, and that A.W. also bears some relation to Cornelius II and IV.

e patient's serum taken four weeks after his discharge hospital gave a negative agglutination reaction with the a A.W., a not unusual finding in these cases.

DISCUSSION

ere was no osteomyelitis of the bone surrounding infected sinuses, though Cooper and Moore (1945) tion that extension to bone is common in infected of dogs and cats. Adenitis was not demonstrated, recovery after adequate treatment was fairly rapid ad of slow and indolent. The patient's general ition was always good, and at no time during his in hospital had he a rise of temperature or pulse-

asal infection of man with *Past. septica* has previously recorded on only two occasions: once by Topley Wilson (1946), and once by Hadorn (1938), who rted a case of meningitis, in a farmer, developing t months after a fracture of the skull involving the t frontal sinus; this patient also recovered.

SUMMARY

case of frontal-sinus infection with *Pasteurella septica* ported.

he organism was sensitive to penicillin in high entration.

The condition responded to adequate surgical treatment combined with vigorous penicillin therapy.

SURVIVAL OF A BABY WEIGHING 24 OZ. AT BIRTH

J. P. BUSH
M.R.C.S.

RESIDENT OBSTETRIC OFFICER, ST. THOMAS'S HOSPITAL, LONDON

THE birth of a baby, at the twenty-seventh week of pregnancy, weighing only 1 lb. 8 oz., which survived, seems worth recording.

On Sept. 20, 1945, a woman aged 23, who had received no previous antenatal care, was admitted to the gynæcological ward of St. Thomas's Hospital with the diagnosis of inevitable abortion. She was then twenty-seven weeks pregnant, her period of amenorrhœa coinciding with the abdominal findings. She had six years previously given birth to a normal full-time infant, and had had one miscarriage at the tenth week of pregnancy five years before. There were no signs of toxæmia, the membranes had ruptured the previous day, and there was a mild pyelitis. She complained of rhythmical abdominal pains, and shortly after admission a female child, presenting by the vertex, was delivered normally. The third stage was completed without incident, and there appeared to be no placental abnormality. The puerperium was uneventful, and the patient was discharged on the fourteenth day after delivery.

At birth this minute infant was vigorous, and respirations soon became established after the air passages had been cleared with a mucus catheter. She was then transferred to the nursery of the obstetric ward, and her weight was found to be 1 lb. 8 oz.

During the first three days she was fed by pipette two-hourly on glucose water with one minim of brandy to one drachm, and took her feeds well. The size of the feeds was gradually increased, and on the third day the infant was taking $1^1/_2$ drachms of 1 in 8 expressed breast-milk with glucose (1 drachm to 10 oz.) two-hourly. The strength of the feeds was gradually increased until on the tenth day the baby was taking 3 drachms of 1 in 3 expressed breast-milk.

The infant was completely cot-nursed, with a radiant-heat cradle and continuous oxygen in an oxygen tent. She was only removed from her cot once a week, when she was weighed. At the end of the first week she had maintained her birth-weight, and at the end of the second week she had gained $^3/_4$ oz.

On the twenty-sixth day regular brandy with each feed was discontinued, and on the thirtieth day she took her first feed of 5 drachms of boiled breast-milk from a Belcroy feeder.

Thirty-two days after birth a small abscess had developed on her right thigh at the site of a previous injection of 1 c.cm. of lobeline hydrochloride which had been given after a severe cyanotic attack after a feed. This abscess was incised and penicillin ointment applied. Penicillin 5000 units was injected intramuscularly every three hours for five doses. The infant was then taking 5 drachms of boiled breast-milk to which brandy had again been added.

The incision wound healed without incident, and on the forty-second day—i.e., six weeks after delivery—the infant weighed 2 lb. 2 oz. She gained a further 2 oz. by the end of the following week, by which time her feeds had been increased to 6 drachms of boiled breast-milk three-hourly from the Belcroy feeder. She occasionally had a slight blue attack after a feed, but usually tolerated her feeds well.

association between characters—e.g., absence of the macula and aniridia, or harelip and cleft palate—may be due to a common genetic or environmental origin. To establish linkage, the repulsion phase as well as that of coupling between the two characters must be observed.

References to parallel conditions known to animal geneticists are scattered freely through the text, and should specially interest those to whom such work is not readily accessible. Readers can be grateful indeed to the author for assembling the massive published work, and for his conscientious summaries of papers. The result is emphatically not a textbook suitable for teaching human genetics but it is of immense value treated purely as a work of reference.

Penicillin Therapy

Including Streptomycin, Tyrothricin and other Antibiotic Agents. (2nd ed.) John A. Kolmer, m.s., m.d., f.a.c.p., professor of medicine, Temple University. New York and London: D. Appleton-Century. 1947. Pp. 339. 30*s.*

Our knowledge of the antibiotics and their applications in therapeutics has reached a level where any book devoted to them must be either a symposium or a compilation. Professor Kolmer has chosen the latter, and the result justifies his preference. He describes the pharmacology and bacteriology of antibiotics in some detail, but the greater part of the book deals with their use in clinical medicine; in a useful and interesting chapter he discusses their employment in veterinary practice. He gives standard methods for laboratory control and assay but covers commercial production in general terms only. His references are well chosen and he treats with judgment subjects which are still open to debate. Published work of alarming proportions is here reviewed in reasonable space, and the book gains wherever the author has drawn on his personal experience—for example, in the chapter on methods of administration. The chapters on antibiotics other than penicillin will be specially welcome to English readers, since no other reasonably complete account has yet appeared.

Thorpe's Dictionary of Applied Chemistry

(4th ed.) Vol. vii. *Iodazide—Metellagic Acid.* Editor: M. A. Whiteley, d.sc., f.r.i.c. London: Longmans, Green. 1946. Pp. 629. 80*s.*

New volumes of the fourth edition of Thorpe's Dictionary continue to appear despite present-day difficulties. This, the first to be under the care of the new editorial board, contains like its predecessors much valuable stuff. The articles on iodine, vitamin K, keratin, lactic acid, lipins, isoelectric point, and membrane equilibria are specially noteworthy, while those on lard, margarine, and meat-extract are most informative, and the little treatise on liqueurs irresistible. Though there is much "pure" chemistry in the work, medical and biological chemistry are treated as important parts of "applied" chemistry; hospitals and universities may not realise this fully and an extra word or two in the title might help them. Moreover, short up-to-date summaries of the biochemistry of some organic compounds, and even of metals, might well be added, for the benefit of the biochemist, to the existing articles—for example, to malic acid, malonic acid, and magnesium in this volume. Since biochemical concepts are changing rapidly, it is inevitable that some of the biochemistry given should already be out of date. Finally, a firm line might be taken by the editors over the difficult question of the notation for configuration and optical rotation of organic compounds.

Practical Physiological Chemistry (12th ed. London: J. & A. Churchill. 1947. Pp. 1323. 50*s.*).—Mr. Philip B. Hawk, ph.d., with his new collaborators Mr. Bernard L. Oser, ph.d., and Mr. William H. Summerson, ph.d., has completed the latest revision of this important textbook. Many of the chapters have been written afresh, and all have been corrected in the light of modern knowledge. New sections have been added on the polarograph, isotopes, sulphonamides and antibiotics, the Warburg tissue-slice procedure, photometric analysis, electrophoretic fractionation of the plasma proteins, and new vitamins, new quantitative methods for analysis of blood and urine, and several other subjects.

New Inventions

AIDS TO BONE SURGERY

Brace-handle Screwdriver

Screwing home several screws in a bone witl ordinary screwdriver can be tiring and may add app ably to the length of an operation. This can be mitig by amputating the hand-piece of a screwdriver fitting a brace to the end (fig. 1). The screw-holding used here is that made by the London Splint Co.

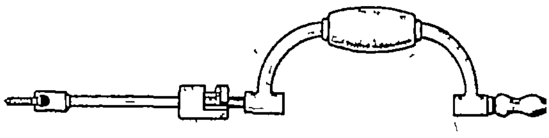

Fig. 1—Brace-handle screwdriver.

This brace-handle screwdriver has been used now nearly five years in a large series of bone-grafting plating operations. There are only two disadvanta First, if an ordinary Lowman clamp is used, it is diffi to insert the screws nearest the clamp, as the brac obstructed by its handle; an angled clamp overco this difficulty. Secondly, some screws may not fit screwdriver.

Apparatus for Estimating Screw Length

When a hole is being drilled in a bone for a screw wi power drill, it is helpful to know the moment when drill pierces the deep cortex. The apparatus illustr in fig. 2 does this in a simple manner.

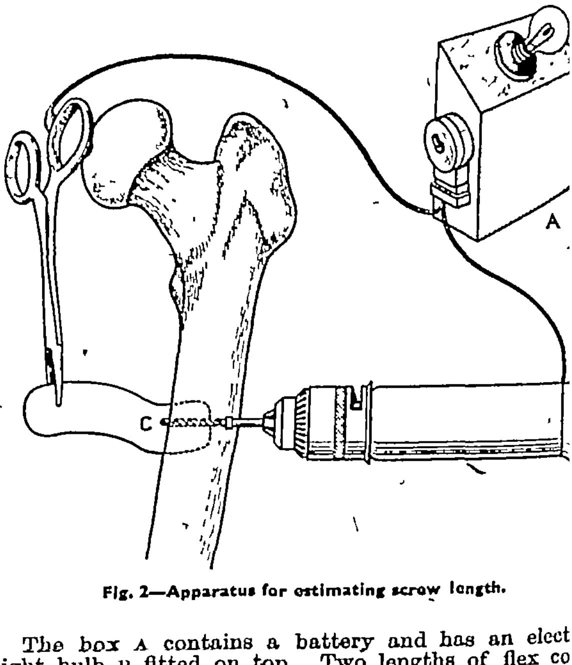

Fig. 2—Apparatus for estimating screw length.

The box A contains a battery and has an elect light bulb B fitted on top. Two lengths of flex co from the box; one is fitted to the drill handle, the ot to a retractor placed on the deep side of the bone. Wl contact is made between the drill point and the retrac at C, the bulb glows. A small rubber band, fitted o the drill before operation, is then moved down until i in contact with the cortex. The distance between t rubber band and the drill point is the length of scr required.

The screwdriver was made for me by Messrs. A. Hawkins & Co. Ltd., of New Cavendish Street, W and the screw estimator in the works department of t Royal Northern Hospital.

Reviews of Books

Its Relation to Congenital Hemolytic Disease and Intragroup Transfusion Reactions

DITH L. POTTER, M.D., PH.D., assistant professor of thology, University of Chicago. Chicago: Year Book ublishers. London: H. K. Lewis. 1947. Pp. 344. 30*s.* 6*d.*

s not the least of the merits of this good little book it makes the nomenclature of the Rh and Hr subs quite clear. A general survey summarises the important aspects of the Rh factor, and a detailed n quotes published work. The survey, though 20 pages long, covers all the general reader needs to about Rh, without omitting any of the more licated aspects of the subject, such as the Rh oups, the place of Hr, and the rôle of blocking odies. The detailed section begins with a historical y of our knowledge of blood-groups and transfusion ions. The properties of Rh antigens and antibodies liscussed, and the schemes of Wiener and Fisher to in the inheritance and relation of the subgroups are set out with clear diagrams. Wiener's table of the bilities in cases of disputed parentage is reproduced. various schemes of nomenclature are compared, but ssor Potter rightly points out that for clinical cation it usually suffices to know whether a person's l is positive or negative when tested with the lard anti-D (anti-Rh$_0$) serum. Some intriguing es on racial incidence are given: the Basques have loubtful privilege of the highest proportion of Rh-tives (33·6%); in the Far East and Polynesia st 100% are Rh-positive; American whites are ly Rh$_1$ (CDe), American negroes Rh$_0$ (cDe), and nese Rh$_1$ Rh$_2$ (CDE); while chimpanzees' blood not react with Rh antigen at all. The way transn reactions are produced by Rh immunisation is oughly discussed, and it is noted that pregnancy uces immunisation much more effectively than mpatible transfusion. Potter does not consider that "biologic" test for anti-Rh agglutinins is justifiable that the blocking antibodies have been discovered; nond's slide technique is usually adequate. The olytic disease of infants is dealt with at length in ters detailing its ætiology, clinical forms, prevention, tment, and post-mortem findings. There is a final ter on technique and a bibliography of 794 references. book has many good illustrations, the style is easy readable, and it can be confidently recommended hose who want to know about Rh.

ical Emergencies

(3rd ed.) CHARLES NEWMAN, M.D. Camb., F.R.C.P. London: J. & A. Churchill. 1946. Pp. 117. 10*s.* 6*d.*

EDICAL emergencies are among the most dramatic lents in medical practice; for the general practitioner, ever, they are relatively rare. This little book gives what he needs—a brief account of the conditions what to do for them. All the commoner emergencies ch as poisoning, asphyxia, and coma—are covered, this new edition is on the whole well up to date, gh the rapid advance in our knowledge of penicillin already outstripped it in places: there is, for instance, reference to the use of penicillin in the treatment of nulocytosis, or of heparin in the treatment of mbophlebitis. The nikethamide group of drugs perhaps erve more mention than they receive, and a reference the rapid response of some resistant cases of asthma theophylline ethylenediamine would enhance the ue of the section on asthma. The statement that gestive failure is common in pneumonia" is surely eading. Taken as a whole, however, this is a book ch the practitioner will find it wise to keep by him.

entials of Neuro-Psychiatry

DAVID M. OLKON, S.B., A.M., M.D., associate professor of psychiatry, University of Illinois. London: H. Kimpton. 1945. Pp. 310. 22*s.* 6*d.*

N outspoken, prejudiced textbook like this is eshing, after the many tediously impersonal ations to conformity. Professor Olkon's prejudices y be recognised from his comment on psychodrama: ychiatry is suffering from so many isms, panaceas, dogmas, etc. that one more innovation does not actually do great harm"; and from the statement in his preface that "the many inconclusive doctrines, speculations as to mental operations, theoretical and rhetorical opinions as to mental modalities, and fanciful ideas as to how these arise," have been intentionally left out of his book. Changes in the capillary vessels of the skin have been studied by Dr. Olkon for many years; he devotes a long chapter to the description of his methods of observing these and the consequent findings, especially in schizophrenia. Though unconventional, his book is not eccentric; the psychiatry it teaches is intelligently, if narrowly, organised; and the reader is offered evidence and references for the numerous statements on unsettled or recently developed topics.

Human Genetics

R. R. GATES, D.SC., F.R.S., emeritus professor of botany, University of London. London: Macmillan. 1946. 2 vols. Pp. 1518. £5.

GENETIC factors in the ætiology of disease have, in the past, been more of academic interest than of practical significance to the doctor; but advances in knowledge of heredity in animals and man have lately been so rapid that medicine now depends on genetic principles in certain fields, notably in the treatment of some hæmatological and biochemical anomalies. No comprehensive, authoritative, accurate, and up-to-date account of the whole of human genetics is available at present, largely because the field is so enormous: an expert in serology, for example, would hesitate to write a textbook on inherited eye diseases, and a cytologist on neurological defects. Professor Gates has valiantly attempted to give a complete account of our knowledge in one book, albeit two volumes of over 700 pages each; but though the reader will find these a storehouse of references—some thousands of papers are abstracted in the text—he will search in vain for guidance in evaluating the work summarised.

Professor Gates approaches genetics from the standpoint of a botanist with exceptional knowledge of some polyploid species, and inevitably his outlook on medical problems is limited by lack of clinical and pathological experience. For example, taste deficiency for phenylthiourea, present in a third of the population, is classed as a hereditary disease of the nervous system; neurofibromatosis is described in the chapter on cancer; and the syndrome of tuberose sclerosis and adenoma sebaceum is treated as two separate entities—under skin and teeth abnormalities and under nervous diseases. Fortunately the excellent index compensates for this lack of coherence in arrangement—a defect which the author regrets in his introduction.

The views expressed by Professor Gates on questions of race biology are somewhat rigid. Eugenics, he says, has never contemplated mixture of races as a desirable future for mankind; and he supports this contention by stating that chromosome rearrangements have occurred in isolated races of man, as in different species of drosophila. In spite of his eminence as a biologist, medical readers not expert in the subject will be well advised to treat his generalisations on human genetics with reserve.

To take one example, a pedigree of epidermolysis simplex is shown and interpreted as an example of Y-chromosome inheritance from fathers to all their sons. However, a footnote reports that recently an unaffected female in the same family has had an affected son. This is explained by saying that the gene has crossed over on to the X-chromosome; but since the condition is, in any case, commoner in males than in females and sometimes skips a generation, it may be sex-influenced and not sex-linked at all.

Throughout the book too much attention is given to the possibility of crossing over between the X and Y chromosomes in man; and the fact that pedigrees of apparently the same condition are often on record, suggesting different types of inheritance, leads the author to the explanation that autosomal genes can become sex-linked by "simple" translocation. There is no reason to doubt that in man, as in other animals, quite different genes can give rise to similar end-results from the clinical aspect. Altogether, the question of linkage in human genetics is presented in a misleading manner. Thus,

TRADE MARK
'ASCABIOL'
BRAND

benzyl benzoate emulsion

For the treatment of scabies, the patient has a hot bath and with a soft brush applies 'Ascabiol,' a non-irritating preparation of benzyl benzoate free from danger of dermatitis, to all parts of the body except the face and head. If the application is thorough, one application should suffice.

'Ascabiol' is supplied in containers of 4 oz. and 80 oz.

Nutritional safety
during weaning

As the infant's introduction to solid food, and as a basis of the diet during the subsequent months, there is no more suitable preparation than Farex. The usual starchy predominance of cereals is balanced in Farex by an increased proportion of protein: in addition, Farex supplies minerals — assimilable iron, calcium and phosphorus — and a useful amount of vitamin D (1,000 i.u. per oz.). With Farex and milk as the staple ingredients, weaning to solids is reduced to its simplest and safest terms. Please help to ensure sufficient Farex for weanlings by prescribing it only for them.

GLAXO LABORATORIES LTD. · GREENFORD · MIDDLESEX · BYRon 3434

Of their 7 failures 5 were in patients who had been inadequately treated with penicillin before coming under observation. Their experience emphasises the lesson that full doses of penicillin must be given as early as possible in this disease. To await the classical picture is to court disaster. Constant watchfulness for the earliest manifestations, repeated blood-cultures in suspected cases, and the administration of full doses of penicillin for at least 4–6 weeks are the basic rules for the practitioner to follow if his patients with subacute bacterial endocarditis are to recover. But the best results will not be attained until every dental extraction and every respiratory infection in a patient with valvular disease of the heart are routinely treated with full doses of penicillin.

Statistics in Medicine

It is sixty years since Sir William Harcourt proclaimed that "we are all socialists now." A "real" socialist of that time said this was just a rhetorical falsehood; and even now there are men of mark, like Mr. Churchill and Lord Woolton, who are not whole-hearted socialists. But Sir William's flourish had a kernel of truth. If Lord Moran were to say of the fellows of the Royal College of Physicians, "we are all statisticians now," the president of the Royal Statistical Society might mutter "rhetorical falsehood!"; but, as Prof. Bradford Hill pointed out in a recent address,[1] our profession is at least more statistically minded than it was a generation ago; and whether we like it or not we doctors are confronted by problems which can only be solved, if they can be solved at all, by statistical methods.

The provision of statistical controls is much more difficult than many people think. As an example of the difficulties Professor Hill cited a series of cases of otitis media in which mastoidectomy was necessary in 15% of the cases where the patient had been treated with a sulphonamide but in only 9% where sulphonamides were not exhibited. This was a "natural" series; the patients were not sorted by lot into those who were or were not to receive sulphonamides; they were treated as, from judgment based on signs and symptoms, the doctor thought best. Hence one would expect a larger proportion of patients seriously ill in the treated series. This (when it is pointed out) is obvious. It may not be quite so obvious why tracing the children born to mothers suffering from rubella may give quite a different answer from that found by tracing back the mothers of children suffering from the congenital defect which there is good reason to think may depend on the maternal disease The second method may make it probable that the particular defect is only produced when the mother of the child had rubella early in the pregnancy; the first is needed to enable us to assess the practical importance of this liability —what proportion of children born under the disability of the mother suffer from the defects. Still more difficult is the control of tests of prophylactic measures, such as protective inoculation against whooping-cough. A mere mass comparison of results in families whose mothers volunteered with results in families whose mothers refused is not enough. There may, for instance, be differences in the size of far and therefore of exposure to risk.

Puzzles like these can be solved by the applic of common sense, which is a by no means con endowment. Indeed all that is meant by the pl is that no technical *statistical* knowledge is ne What is needed is an intelligent appraisal of possibilities that an answer to the question ask Did the treatment do good?—might be "Yes reasons other than the treatment. This app needs intelligence *and* medical knowledge of possibilities. That is why knowledge of the bilities should be first in line when a large experiment is planned. Of course technical stati knowledge is also important. A professional s tician may be able to tell much more quickly tha amateur whether the scale of a properly pla experiment is adequate to give a reliable answer the medical investigator has a sound knowled the technique of modern statistical analysis it make his work so much the more convincing. no medical man should be scared away from rese in his field—whether clinical or sociological—be he has no passion for algebra and eyes characte functions with an indifference bordering on avers

Nitrogen Mustards

"*Poison Gas Treatment for Cancer*" ran a hea in a recent daily newspaper.[1] Little has so far published in Britain about the therapeutic applica of mustard gas and related substances, because o veil of secrecy that has obscured all poiso research; but American research-workers seer have been quicker in casting off such restrictions, last year a good deal of their information was rele Thus, though the British work mostly remains bı in unpublished reports, it is possible to summ some of the scientific evidence behind the newspa startling announcement.

Experience in 1914–18 with mustard gas had sh that it was toxic to blood-forming tissues. In and succeeding years a group of closely allied pounds, the "nitrogen mustards," were being prep in factories in this country, and workers who exceptionally exposed to these substances or burnt by them showed a depressed white-cell co the lymphocytes being especially lowered, while s had a low granulocyte count and later anæ When the exchange of information between Bri and the U.S.A. began, these findings were pa across the Atlantic, and on both sides research the toxic effects was pressed on, beginning animals. The pharmacology and therapeutic use nitrogen mustards were discussed last year by Gil and Phillips [3] in America. Two substances of spe importance have emerged; their chemical names *tris*(β-chloro ethyl)amine hydrochloride and metl *bis*(β-chloro ethyl)amine hydrochloride These s stances—or rather their breakdown products—pro to have a special predilection for actively divic cells. Auerbach and Robson [3] experimented w the drosophila fruit-fly; in the adult fly the c organ with actively dividing cells is the gonad, nitrogen mustards were found to have a select

THE LANCET

LONDON: SATURDAY, JUNE 28, 1947

Infective Endocarditis

It is four years since the FLOREYS[1] first reported that penicillin sterilised the blood in patients with subacute bacterial endocarditis. In spite of the war-time shortage of penicillin nearly 500 cases treated with penicillin have since been published. The immediate success of this form of therapy in a previously incurable condition naturally led to its enthusiastic but indiscriminate adoption, and it was not until controlled studies, such as that of the Penicillin Clinical Trials Committee of the Medical Research Council, established the optimum dosage, method of administration, and duration of treatment that consistent results were obtained. Subsequent reports have confirmed that penicillin controls the infection in a way that has never before been possible. KOLMER,[2] for instance, recorded a 68% recovery-rate among the cases so far reported—292 recoveries out of 25 cases—while in 34 unselected cases subsequently described by PRIEST and colleagues[3] 22 patients (5%) were free from evidence of active disease 13–35 months after treatment. The revolutionary change in outlook is well illustrated by SEABURY's[4] series of 165 cases seen at Ann Arbor between 1934 and 45. Of the 66 patients treated before the introduction of the sulphonamides none recovered; of the 53 patients treated with sulphonamides 4 recovered; of 13 treated with combined chemotherapy and pyretotherapy 2 recovered; whereas of 12 treated with penicillin 7 recovered. These numbers are small, but since they come from the same hospital they provide a fair comparison.

Opinion is still divided on the best method of administration. The Americans mostly favour continuous intravenous infusion.[2] PRIEST and colleagues[3] support this view because they found that in some patients blood-cultures were positive three hours after an intramuscular injection of penicillin, whereas with continuous intravenous infusion cultures were repeatedly negative. They claim that with this method venous thrombosis occurs only if the penicillin is dissolved in distilled water or 5% dextrose, and not if it is dissolved in isotonic saline. Even in America, however, the experts differ. Thus SEABURY[4] noted thrombophlebitis in all of 6 patients treated with a continuous intravenous drip, so he switched over to a continuous intramuscular drip; and THILL and MEYER[5] found three-hourly intramuscular injections satisfactory. In this country the intramuscular route, whether intermittent or continuous, is usually preferred; but continuous intravenous drip, where feasible, is probably best in severely ill patients, at least in the initial stages.

Next the total amount to be given and the duration of the course have to be decided. In the M.R.C. investigation CHRISTIE[6] found that of 19 patients receiving 1,000,000 units daily for five days all but one relapsed or died, whereas of 19 given 500,000 units daily for three to four weeks only 5 did so. As a result of further experience he recommends[7] that 500,000 units should be given daily for four weeks provided the causative organism is not more than ten times as resistant to penicillin as the Oxford staphylococcus. PRIEST and colleagues[3] advise a minimum of 500,000 units daily by intravenous drip for at least four weeks, and raise this to 1,000,000 units daily if the disease has lasted more than twelve weeks. The best results, in their experience, have been attained when the serum level is 100 or more times greater than the in-vitro inhibition level of the organism. If intermittent intramuscular injection is used, they recommend at least 800,000–900,000 units daily, divided into twelve or eighteen doses. Using a continuous intramuscular drip SEABURY gives not less than 500,000 units daily, or 2,000,000 units daily if positive blood-cultures persist after three days' treatment. There is general agreement that treatment must be continued for at least a month, and that neither sterilisation of the blood nor a normal temperature is a reliable guide to the adequacy of dosage. A normal leucocyte-count is not of much value in assessing success, but a persistently high or a rising count, in the absence of complications, is an indication of insufficient treatment, and if the leucocyte-count rises steadily after treatment has ended it should be reinstituted. A simultaneous rise in the sedimentation-rate is an additional strong indication for renewal of treatment in large doses.

Some other practical points arise out of the American reports. It seems that the penicillin-sensitivity of the infecting organism is a useful guide to dosage but of little significance in prognosis. Thus, PRIEST et al.[3] noted that there were 5 deaths among 12 cases in which the organism was inhibited in vitro by 0·06 unit of penicillin per c.cm. or less, whereas there were also 5 deaths among 9 cases in which the inhibition level was 0·07 unit per c.cm. or more. These observers found that a constant fluid intake led to less fluctuation in the serum concentration of penicillin, and they therefore limited their patients to 800 c.cm. of fluid daily, given at the rate of 100 c.cm. two-hourly from 7 A.M. to 9 P.M. In most cases nothing is gained by combining sulphonamides with the penicillin—indeed, PRIEST and colleagues say that sulphonamides are contra-indicated because of the risk of renal complications. On the other hand, sulphonamides will occasionally be of value, as when the causative organism belongs to the para-influenzal group. PRIEST cured one such case with penicillin plus sulphamerazine, but he and MCGEE[8] now look on streptomycin as the drug of choice in infections with gram-negative organisms insensitive to penicillin. Anticoagulant therapy adds little, if anything, to the value of penicillin. THILL and MEYER, after treating 22 cases, 13 of them with penicillin and dicoumarol and the remainder with penicillin alone, concluded that the occasional advantage of dicoumarol was outweighed by its disadvantages.

STORIES OF THE ROTUNDA

THE achievement of the Rotunda Hospital over two centuries—soon to be celebrated by an international congress—must always be linked with the memory of Dr. Bartholomew Mosse, whose genius and initiative made possible the foundation and development of the famous institution. In a book[1] which might well have been called "The Romance of the Rotunda," Mr. C. P. Curran describes Mosse's burning enthusiasm for this cause, which carried him along like a strong tide, despite many obstructions, to its fulfilment. The beginning of the eighteenth century in Ireland was not particularly encouraging to an idealist; but Mosse, returning from travel on the Continent, lost no time in establishing a hospital "for poor lying-in women" and found the way to pay for it. Himself a musician of no mean order, he conceived the happy idea of calling St. Cecilia to his aid, and in due course the finest vocalists and instrumentalists in Europe were engaged for a series of great concerts. In addition Mosse, ever on the alert to hold the public eye and ear, arranged for all manner of lighter entertainment, until Dublin became for the time the musical centre of these islands, while London languished in the shade. And Mosse did all this not for his own honour and glory but to further the growth of his hospital.

The Rotunda, with its fine architecture, is one of the sights of Georgian Dublin; and the round pillared hall, which gives it its name, has been the scene of concerts, lectures, and balls for two centuries—a constant fountain of income for the great charity beside it, and a means of keeping this charity prominently before the eyes of the citizens. The hospital itself, the first of its kind in Eire, and for years the largest maternity hospital in the British Empire, has been the training ground of thousands of medical men from all over the world. In a commemorative volume[2] written in honour of the bicentenary, Prof. O'Donel T. D. Browne gives a comprehensive picture of its history. Its constitution is peculiar: it is governed by a "master," who is already a recognised gynæcologist, and who is aided by two assistant masters whom he appoints, and who serve for three years. The master holds his post for seven years, and when he retires from it is usually appointed to the staff of one of the teaching hospitals of the city. Professor Browne, who has himself been an assistant master, gives a biographical account of all the masters, from Mosse to the present holder of the appointment, Ninian Falkiner. He relates the history of obstetrical advances over 200 years to the work of the hospital and to the wisdom, or otherwise, of the master at the time. In chapters on puerperal fever, operative midwifery, anæsthesia, and eclampsia we are given a valuable and accurate description of each advance, together with an unbiased account of the way in which it was received by the Dublin school. Naturally the record of advances in the treatment of eclampsia is particularly vivid, and Tweedy's pre-eminence gets the emphasis it deserves. His treatment, indeed, has been the main modern contribution of the Rotunda school to the saving of women in childbirth. The description of the early struggles of the hospital and its financial ups and downs is graphic, and running from those early days till recent times is the story of the fight against puerperal fever, which this maternity hospital like every other fought through the centuries—a fight which has been decisively won only in our own time.

GLUTAMIC ACID AND MENTAL FUNCTION

IN 1945 American workers showed that the ad
of the amino-acid *l*-(+) glutamic acid to the
enabled rats to learn a maze much quicker than
controls,[1] and it also increased the percentage of a
capable of overcoming an increasingly difficult se
obstacles in search of food.[2] The effect of glut
acid on mental function has since been tested in chil
and adolescents.[3] "A universally increased mental
physical alertness" had previously been observed
patients treated with glutamic acid[4] for petit ma
condition which seemed to be improved by
treatment, though the amino-acid has no effect
experimental convulsions.[5]

Zimmerman and his colleagues tested the effect
glutamic acid on nine patients aged 16 months to
years, seven of whom had convulsive disorders and
mental retardation without convulsions. These pati
were given verbal, motor, and personality tests be
and after a 6 months' course of glutamic acid.
dose ranged from 6 to 24 g. per day, with an aver
of 12 g. daily (4 g. t.d.s. by mouth). The subj
showed "impressive changes" in their intelligence sco
with an average increase of 8 in the intelligence quoti
after glutamic-acid therapy, with no negative deviat
at all. The results were regarded as highly signific
In all subjects sharp positive increments in mental
were reported after treatment, and in the low-g
defectives treated the rate of increase was faster
is expected in normal children. Thus three subj
gained 7, 14, and 16 months in mental age in th
months' period. Moreover, Rorschach records sho
that "glutamic acid has an effect on mental functio
which not only is reflected in verbal and performa
test scores but can be observed in rather basic persona
changes." Although the number of patients investig
was small and the period of test somewhat short,
suggested "that glutamic acid may have a gen
facilitating effect on mental functioning in hu
subjects." The glutamic acid sometimes caused gas
distress, and it should be noted that motor activit
increased by large doses of glutamic acid, produ
restlessness, overactivity, and sleeplessness.

The *l*-(+) glutamates are readily water-soluble
stances with a characteristic meat-like flavour.
sodium salt is manufactured and consumed as a
and condiment in China and Japan and to some ex
in the U.S.A. Numerous patents for the use of *l*-
glutamates in the food industry are in existence. Gl
mic acid occurs abundantly in the normal human
especially in milk, where it makes up 22% of the cas
and the greater mental alertness of school-child
receiving extra milk may possibly be connected
the effects of glutamic acid. A pint of milk cont
3–3·5 g. of glutamic acid, so the average dose used
Zimmerman and his colleagues (i.e., 12 g.) would
contained in only about 3–4 pints of milk.

The rôle of *l*-(+) glutamic acid in the metabol
of nervous tissue has also been studied. Weil-Malher
discovered in 1935 that this amino-acid is the only
oxidised directly by brain, and that the enzyme resp
sible is bound in the cell. But he doubted whet
glutamic acid is present in sufficient amounts in br
to compete with carbohydrate as a fuel. He theref
suggested that the enzyme (glutamic acid deamina

on gametogenesis ; in the developing fly, many hose tissues were still growing, the effect was h more widespread. In normal adult man, the e-marrow and the lymphatic nodes are the most rtant sites of active cell division, so it is not ising that these are the tissues earliest affected itrogen mustards. All these facts suggested that nitrogen mustards might be active against pro- ating neoplasms. They were given to mice with splanted lymphosarcomata—and the tumours ppeared. The next step was to attempt the tment of human disease. This had to be done carefully because the mustards are powerful toxins and because they are very liable to cause mbosis at the site of injection Eventually a technique was worked out and the first results e been reported in America by Rhoads,[4] and by obson, Dick, and others.[5]

ethyl-*bis*(β-chloro ethyl)amine is the drug most n used. As a rule it is given in a dose of mg. per kg. body-weight intravenously ; to avoid mbosis—and excessive concentration—a rapidly ing saline drip is set up, and the dose, already olved in 10–20 c.cm. saline, is slowly injected ugh the saline delivery tube, taking 2–3 minutes ; course" is one daily dose for three or four days. re are various toxic effects. An early symptom usea and vomiting coming on within a few hours, some patients get this after every dose. The first d change is lymphopenia, and then the granulo- s are diminished ; with this dosage the anæmia uced should be only slight ; the platelet-count is n lowered. These effects are temporary and after ut five weeks hæmopoiesis is back to normal. So as the research has proceeded—the longest follow- s two years—it seems that doses of this nitrogen tard can be repeated without the danger of cing an irreversible aplasia of the blood-forming ues. Overdosage, or giving the drug in too centrated a form, is liable to cause serious destruc- of hæmopoietic and lymphatic tissues, and fatal stic anæmia may be the result.

itrogen mustard treatment has now been given to ents with several neoplastic diseases, but signifi- t success has been obtained only in diseases olving the blood-forming or lymphatic tissues. als with metastatic mammary and cervical carci- a and with melanosarcoma have not been ouraging, though Rhoads reports a temporary ission with "anaplastic carcinoma" of the lung. best results have been obtained in Hodgkin's ase, of which Dr. ApThomas and Dr. Cullumbine ort 21 cases in this issue. All their patients, even se with the most advanced disease, showed some efit in the three to eight months of observation. obson et al.[5] report 27 cases, in 8 of which the ient died without responding to mustard or X-ray atment, but the others showed significant reduction gland masses, including abdominal and thoracic nds ; enlargement of liver and spleen regressed, emia remitted, and the patients were greatly proved in general condition : in 4 patients response s obtained to mustard treatment when X rays had led. The effects lasted six to eight weeks, and then other course of two or three daily injections had to be given. With lymphosarcoma, 4 out of 6 patients had clinical remissions lasting three to eighteen months—a result comparable with that gained by X-ray treatment. Acute leukæmia is as unresponsive to nitrogen mustard as to other therapy. With chronic lymphatic leukæmia the results have not so far been as satisfactory as with X rays ; in chronic myeloid leukæmia the results have been variable, in some cases a remission lasting several months being obtained, while in others there was only transient symptomatic improvement although the leucocyte count was reduced. In polycythæmia vera nitrogen mustard treatment induced a lowering of the red-cell count and symptomatic improvement lasting a few months. The treatment had no effect in multiple myeloma.

In short, the results so far show that the nitrogen mustards are of no value in the treatment of carcinoma ; they will induce regression in some neoplastic or neoplasm-like conditions involving the blood-forming and lymphatic tissues, but these effects are temporary and the treatment must be repeated every few weeks or months—very like X rays. The best results have been in the treatment of Hodgkin's disease and perhaps polycythæmia vera. The mustards are dangerous toxic substances whose main effect falls on the hæmopoietic tissues, and the margin between safety and disaster does not seem to be very wide ; as Rhoads points out, the extent of this effect is the limiting factor in their use and it may exceed the effect on a tumour. They are emphatically not for general use, and their applications must for the present continue to be studied only in special clinics. Their importance lies in the fact that here are substances that in vivo break down liberating agents with a selective action on actively dividing tissue, and therefore on tumour tissue, and that it may be possible to obtain substances with a greater margin of safety—that is, with a still more selective action. If a safer substance cannot be found, the use of nitrogen mustards is likely to be confined to the palliation of cases of Hodgkin's disease in which X rays have already failed.

Pensions Under the Act

In 88 pages the Minister of Health has presented to Parliament his superannuation scheme for the National Health Service. It is designed, he says, to provide benefits comparable to those obtainable by established civil servants under the Superannuation Acts, 1918–46, the major ones being a pension, a lump-sum retiring allowance, and a widow's pension. To secure these benefits, all members of the service (other than manual workers) will contribute 6% of their remuneration, as defined. Doctors employed by regional hospital boards, including specialists, will be entitled on retirement to a pension amounting to one-eightieth of their average remuneration for each year of service up to 40, and a retiring allowance amounting to three-eightieths. General practitioners will be entitled to a pension amounting to 1½% of their remuneration in each year of service—"remuneration" to include all payments made in respect of general medical, dental, or pharmaceutical services, less practice expenses—and a retiring allowance amounting to 4½%. Allowances are reduced by two-thirds where a widow's pension may be payable. Practitioners holding life-assurance policies may apply for exemption from the scheme, and as a contribution to the maintenance of their policies may receive from the Minister an amount equal to 8% of their remuneration.

REINFORCEMENT IN DIPHTHERIA PROPHYLAXIS

If the value of mass immunisation in the control of diphtheria still required proof it would be found in the recent statement of the chief medical officer of the Ministry of Health[1] that " of every 5 children suffering from diphtheria during the years 1942–45 inclusive 4 had not had an immunisation course, and of every 30 deaths from this disease in the same period 29 were of non-immunised children." But, ignoring the small percentage refractory to immunisation and those whose course may have been incomplete, there still remain children who, in spite of a full primary prophylactic course, do contract diphtheria—usually mild, but occasionally severe or even fatal if the infecting strain is highly virulent and diagnosis late. The immunity conferred by diphtheria prophylactics wanes with time, and although it is known that the virulent gravis and intermedius strains of *C. diphtheriæ* can sometimes break down the barrier of immunity as assessed by a negative Schick test, clinical diphtheria among the previously immunised is usually an indication that the level of antitoxic immunity has fallen dangerously low. Hence the importance of the reinforcing dose, or *injection de rappel*, of the prophylactic which will secure for the child immunised in infancy a high level of immunity at the time of school entry and throughout school life, with its greatly increased risks of infection.

In a circular letter to medical officers of health Sir Wilson Jameson suggests reinforcing doses at the age of 4 to 5 and again at 10 years. He points out that, during 1945, of 593 children who died of diphtheria only 36 were reported to have been immunised, and of these 36 about 30 had not received a reinforcing dose subsequent to primary immunisation in infancy. Current preparations of A.P.T., the prophylactic of choice for children, produce a high degree of immunity and cause fewer and less severe reactions than was usual in the past. But while primary immunisation may be reactionless, when used for reinforcement A.P.T. sometimes provokes unduly sharp reactions. Hence the chief medical officer suggests that for this purpose in children T.A.F. (which is less likely to cause reactions) might be preferable. Reinforcement doses of this prophylactic can now be obtained free of charge from the same sources as A.P.T.

NURSES FOR THE ELDERLY

Excluding its county boroughs, Kent has a population of some 125,000, and of these at least 2500 people, or about 2%, can be classed as chronic sick and are known to need institutional beds. Dr. Elliott,[2] the county M.O.H., says that last January over 800 patients were waiting for beds (the number has since risen to 928), and some 1800 were already in hospitals or institutions. He speaks of the nursing problem as being especially heavy, since about " 20% of the patients are incontinent both of urine and fæces and over half are bedridden." A recent study of work in the West Middlesex Hospital[3] suggests, however, that these particular nursing problems could be reduced : experience there has shown that with active treatment the number of bedridden patients among the chronic sick can be kept between 10% and 20%, and that patients can be trained back to continence much more often than is usually supposed. Lack of nursing staff, of course, hinders proper training of incontinent patients, as it hampers every part of the care of the chronic sick. The solution which comes at once to mind is a well-planned part-time nursing scheme ; but though part-timers are used to supplement the full-time nurses, Dr. Elliott believes that a scheme on the Gloucestershire lines—where the part-time workers are the staff, supplemented by full-timers—could not be applied as it stands to Kent. He estimates that if treatment were to provided for all who require it in the county—incl patients waiting for beds in sanatoria and hospitals, as well as the chronic sick—some 2000 to part-time nurses would be needed. With a county p tion of 125,000, however, this does not seem an o rageous figure ; it would be interesting to know many would be needed for the chronic sick alone. intensive campaign for part-timers has already launched, and will probably alleviate acute difficul especially if the newcomers are shown clearly that t value is recognised.

Dr. Elliott has a further proposal—that he middle-aged and elderly people should be called upon do more for " casualties arising in their own ranks. Experience has shown that older nurses have m sympathy with the aged than young ones, and that t bring more tact and insight to the care of the chro sick. We cannot go all the way with Dr. Elliott w he says that " the younger entrants to the n profession should be allocable mainly to the more stren ous and specialised aspects of nursing, and should, completion of training, undertake periodic duties of oversight and instruction of older and less able n and attendants who would be primarily engaged tending the chronic sick." This implies that nursing the chronic sick is unpleasant and suited only to infe nurses ; indeed, he describes it as " arduous, monotono and at times revolting." It might be instructive to h the comment of a sister in one of the chronic wards the West Middlesex Hospital on that string of adjectiv *Chronic-sick nursing, if properly done, is not only o of the most " strenuous and specialised " but also one the most engrossing and testing forms of nursing, suit certainly to the more mature but emphatically not the " less able " nurses and attendants.* The interest nurses in the care of such patients seems to be directl proportional to the interest of doctors in their acti treatment. As geriatrics begins to attract the more ab members of our profession, it is to be hoped that w and institutions for the aged will also become the reso of the abler of our nursing colleagues.

THE LISTER INSTITUTE

In their annual report just issued the governing bo of the Lister Institute of Preventive Medicine give impressive account of the work accomplished by the st headed by Dr. A. N. Drury, F.R.S., during the past ye The institute continues to house several independe units. The Medical Research Council's blood produ research unit, and its bacterial chemistry unit un Sir Paul Fildes, F.R.S., are still there, and accommodati has also been found for the council's blood-group resear unit, directed by Dr. R. R. Race, and for the bloo group reference laboratory of the Ministry of Heal This last, in the charge of Dr. A. E. Mourant, h concerned itself with the supply of standard A, B, and Rh blood-grouping sera, and it has been prepari to supply the rarer types ; it also undertakes the inves gation of difficult cases. Dr. S. T. Cowan has succeed Dr. R. St. John Brooks as curator of the Natio Collection of Type Cultures, which is still housed Elstree. During 1946 the collection supplied more th 7000 cultures to workers at home and abroad, a helped to re-establish culture collections in several the countries formerly occupied by the Germans.

A royal charter has been granted to the College Midwives, which will in future be known as the Roy College of Midwives.

Dr. Cecil Wall, consulting physician to the Londo and Brompton Hospitals, and archivist and past mast of the Society of Apothecaries, died in London o June 19 at the age of 77.

bably acts in vivo by catalysing the reverse reaction—mely, the synthesis of glutamic acid from ammonia d α-ketoglutaric acid, which in *turn* is known to e in carbohydrate metabolism (Krebs citric-acid le). Both the exogenous and the hypothetical ogenous supply of glutamic acid acquire some signifi- ce in relation to nervous metabolism through the k of Nachmansohn et al.,[7] who showed that the addi- of *l*-(+) glutamic acid to dialysed brain extracts eases the rate of acetylcholine formation 4–5 times, only other substance with a comparable effect being ic acid, which is interesting in view of Weil-Malherbe's rk. Zimmerman and his colleagues also assume that observed effects of glutamic acid are somehow ated to acetylcholine synthesis. However, like some er amino-acids such as aspartic, glutamic acid has en shown to be a sugar-former; though the hypothesis t glutamic acid acts on the central nervous system virtue of its hyperglycæmic action is weakened by e recent results of Klein and Olsen,[8] who found that transfer from blood to brain of *l*-(+) glutamic acid er intravenous injection is much less than that of cose.

PROSTITUTION IN FRANCE

THE shutting of the brothels in France by the decree April 13, 1946, was a confession of failure in the dical control of their inmates. The reasons for this ure are not far to seek. As Gounelle and Girault[9] int out, women in brothels were medically inspected ly twice a week, and tests of the genital secretions d of the blood were done only once in three months, ystem which must prove quite ineffective for women o might have forty clients each day and also might ape inspection by rapid moves from brothel to brothel. e proportion of known cases of venereal disease in ns traceable to brothels has been estimated at 40%, ough in 1942, for example, there were only 1500 nates of brothels as against 5000 registered and ,000 to 80,000 unregistered prostitutes working lependently.

The French had their first large-scale experience doing without brothels after the war of 1914–18, en their Army occupied the Rhineland, where German r did not allow brothels. The general incidence of nereal disease among soldiers remained steady at 6 per 1000, but in occupied territory the incidence s only 0·19–0·28 per 1000. In 1931, at Grenoble, e brothels were closed and the registration of prostitutes s also forbidden; but these measures were supple- ented by the creation of an anti-venereal social service, r the reclamation of prostitutes and the protection of ds, and by the provision of facilities for treatment ter working hours. There followed a remarkable crease in cases of primary syphilis, and, contrary to pectation, there was no increase in sexual offences. unelle and Girault conclude that it is not enough close the brothels. The displaced inmates must be red for and the public enlightened about venereal sease. Infectious contacts must be found and effective eatment supplied conveniently and if necessary free. arly diagnosis is essential, and the patients should tend general clinics to avoid the stigma which may tach to known special centres.

Opponents of the closure of brothels point to the large crease of venereal diseases in France since the decree 1946 was passed, but Gounelle and Girault show, om statistics of twenty large French towns, that the eep rise in incidence began in 1941. Blum[10] reports, wever, that only a small proportion of the registered prostitutes, who are still allowed to practise away from "maisons de tolerance," attend for their periodical medical inspection, and that admissions to St. Lazare have fallen off because arrested prostitutes are sent to the common gaols. The number of arrests has also fallen considerably, but among the women arrested there is a much higher incidence of infectious syphilis and soft sore.

INCIDENCE AND SIGNIFICANCE OF GLYCOSURIA

ONE of the many lessons that we have learned from the 1939–45 war is how ignorant we are of the incidence of disease and of the precise border between health and sickness. The incidence of glycosuria and its relationship to diabetes mellitus is a case in point. Most of the investigations hitherto reported have been done in the United States,[1] but two analyses of British findings—that of Lyall[2] and the one by Dr. Keeping and Dr. Lawrence in this issue—emphasise the uncertainty concerning the real significance of glycosuria. Comparison of these reports must not be pressed too far, for the conditions of the investigations varied considerably; they have all been based on the cases in which glycosuria was detected on routine examination in recruits for the Armed Forces, but in some series many cases of glycosuria had been excluded at a preliminary examination. The age and sex distributions also varied. The salient findings may be summarised as follows:

Reference	No. of cases of glycosuria	Percentage of—		
		Diabetes mellitus	Lag curve	Renal glycosuria
Blotner and Hyde[3] ..	367	56 6	.	9
Keeping and Lawrence	956	18	13 3	65
Lyall[2]	387	15	.	59 4
Peel and Peel[4] ..	115	37	10 4	40
Spellberg and Leff[5] ..	37	24 3	.	..
Wolman[6]	324	6 5	..	..

Thus in the American figures we have proportions of true diabetes mellitus among recruits with glycosuria ranging from 6·5% to 57%, while in Great Britain the range is from 15% to 37%. Among Lyall's 387 cases of glycosuria there were 94 cases which he described as either "borderline" or "doubtfully diabetic." He also included in his series 23 cases characterised by low blood-sugar values and persistent glycosuria even during fasting, for which he suggested the term "renal diabetes."

This mass of data clearly requires further analysis and correlation, but two important lines of research emerge. In the first place, those found to have glycosuria which is not definitely diabetic in origin should be carefully followed to determine whether they develop diabetes mellitus later in life. Secondly, diabetic experts in this country and America should pool their information so as to define criteria for the diagnosis of diabetes mellitus, renal glycosuria, the lag-storage curve (or oxyhyperglycæmia as it is sometimes called), and renal diabetes. The confusion in nomenclature is exemplified by the fact that most American authorities do not recognise the lag-storage curve as a separate entity. Clear indications should be given as to whether the blood-sugar estimations are based on the findings in capillary or venous blood; for, as Keeping and Lawrence point out, there is a significant difference between these two levels.

While the experts are clearing the ground there are two practical lessons for the clinician to bear in mind: that every case of glycosuria requires full investigation, and that only a minority of them will turn out to be diabetic in origin.

provided for all who require it in the county—inclu
patients waiting for beds in sanatoria and ge
hospitals, as well as the chronic sick—some 2000 to
part-time nurses would be needed. With a county po
tion of 125,000, however, this does not seem an
rageous figure; it would be interesting to know
many would be needed for the chronic sick alone.
intensive campaign for part-timers has already
launched, and will probably alleviate acute difficu
especially if the newcomers are shown clearly that
value is recognised.

Dr. Elliott has a further proposal—that he
middle-aged and elderly people should be called up
do more for "casualties arising in their own ra
Experience has shown that older nurses have
sympathy with the aged than young ones, and that
bring more tact and insight to the care of the ch
sick. We cannot go all the way with Dr. Elliott
he says that "the younger entrants to the nu
profession should be allocable mainly to the more st
ous and specialised aspects of nursing, and should,
completion of training, undertake periodic duties o
oversight and instruction of older and less able n
and attendants who would be primarily engage
tending the chronic sick." This implies that nursi
the chronic sick is unpleasant and suited only to in
nurses; indeed, he describes it as "arduous, monoto
and at times revolting." It might be instructive to
the comment of a sister in one of the chronic wa
the West Middlesex Hospital on that string of adjec
Chronic-sick nursing, if properly done, is not onl
of the most "strenuous and specialised" but also o
the most engrossing and testing forms of nursing, s
certainly to the more mature but emphatically n
the "less able" nurses and attendants. The inter
nurses in the care of such patients seems to be di
proportional to the interest of doctors in their
treatment. As geriatrics begins to attract the more
members of our profession, it is to be hoped that
and institutions for the aged will also become the
of the abler of our nursing colleagues.

THE LISTER INSTITUTE

In their annual report just issued the governing
of the Lister Institute of Preventive Medicine gi
impressive account of the work accomplished by the
headed by Dr. A. N. Drury, F.R.S., during the past
The *institute continues to house* several indepen
units. The Medical Research Council's blood pro
research unit, and its bacterial chemistry unit
Sir Paul Fildes, F.R.S., are still there, and accommod
has also been found for the council's blood-group res
unit, directed by Dr. R. R. Race, and for the b
group reference laboratory of the Ministry of He
This last, in the charge of Dr. A. E. Mourant,
concerned itself with the supply of standard A,
and Rh blood-grouping sera, and it has been prep
to supply the rarer types; it also undertakes the inv
gation of difficult cases. Dr. S. T. Cowan has succe
Dr. R. St. John Brooks as curator of the Nat
Collection of Type Cultures, which is still house
Elstree. During 1946 the collection supplied more
7000 cultures to workers at home and abroad,
helped to re-establish culture collections in sever
the countries formerly occupied by the Germans.

A ROYAL charter has been granted to the Colleg
Midwives, which will in future be known as the R
College of Midwives.

Dr. CECIL WALL, consulting physician to the Lon
and Brompton Hospitals, and archivist and past ma
of the Society of Apothecaries, died in London
June 19 at the age of 77.

AMERICAN MEDICAL ASSOCIATION

CENTENNIAL MEETING

FROM A CORRESPONDENT

HE venue of this meeting, from June 9 to 13, was ntic City. Imagine Brighton or Blackpool, but larger scale; take away the promenade and substi- a wooden broadwalk of great width and enormous th devoted solely to pedestrians and those more d who prefer to be wheeled slowly in well-sprung, amatic-tyred, upholstered chairs; flank this broad- k on one side with a perfect sandy beach, large ntic rollers breaking in a froth of spindrift, tents, hers, and all the paraphernalia of the seaside including e mammoth piers, and on the other side with a s of low-built shops containing anything from the t expensive mink coats and jewellery to the apparatus the practical joker; intersperse these shops with erous luxury hotels, more reminiscent of Le Touquet Juan les Pins than our native hostelries; add a con- tion hall which appears to be larger than Olympia or White City; back the whole with a large and arently prosperous town with good shops, banks, boarding-houses: and you may get some idea of the osphere of the place.

tlantic City was chosen because at least 15,000 doctors, t of them accompanied by their wives, and some their families also, were to attend the meeting; wn used to accommodating a very large number of sient guests was the only possible location.

he convention hall was not much used for meetings; e were housed the exhibits of instrument manu- urers, publishers, and drug houses, in a display iniscent of the exhibitions seen at home. Here was the scientific exhibit, where by means of charts, oured transparencies, and other devices including tomical preparations some 1300 items were cleverly succinctly shown.

he American Medical Association had invited a large nber of distinguished guests, representing other dical associations and governments, to attend the eting. The British Medical Association was repre- ted by Dr. Guy Dain, Dr. Charles Hill, Dr. gh Clegg, and Dr. J. A. Pridham. Representatives ne from as far away as Syria, Saudi Arabia, and n; and distinguished clinicians and scientists from ny countries were to be seen wearing on their lapels golden medallion of the A.M.A. with the words nvited Guest" printed in gold on a green ribbon ow the medallion.

he programme of the section meetings covers some closely printed pages in the official manual; and it mpossible to do more than outline some of the titles the more important contributions, in full awareness t the selection may do less than justice to the efforts many men.

n the *section on internal medicine*, the chairman, T. Wearn, delivered a paper on the challenge of ctional disease; R. Fitz gave the centennial address the history of the specialty of internal medicine in the ited States; whilst H. D. Claro, of Chile, the section's eign guest, spoke on the contribution of the laboratory the differential diagnosis of jaundice.

In the *section on surgery*, Sir Heneage Ogilvie, the eign guest, opened the proceedings with a paper titled gastric surgery after one hundred years; he s followed by the chairman, A. Ochsner, who spoke carcinoma of the lung; and the centennial address s given by E. A. Graham, whose subject was a century American surgery. (In each section the centennial dress concerned American work in the section's specialty during the past hundred years.) After some eight other papers authorities from the surgical section and the section on gastro-enterology combined to give a wide-ranging symposium on peptic ulcer.

In the *section on obstetrics and gynecology*, J. E. Eyre, of Montreal, spoke on cervical cytology in the diagnosis of early cancer; E. A. Schumann delivered the centennial address; Alice F. Maxwell, the chairman, gave a paper entitled a medical inventory; the foreign guest, J. Heyman, of Stockholm, spoke on the comparability of material in evaluating results of radiotherapy of cancer of the uterine cervix.

The *section on ophthalmology* heard an address by Sir Stewart Duke-Elder, the foreign guest, witnessed a demonstration of new instruments, and among other matters received a communication from J. G. Bellows and C. J. Farmer on streptomycin in ocular infections.

The *section on laryngology, otology, and rhinology* were addressed by G. Ewart Martin, of Edinburgh, the foreign guest, on the present position of bronchœsophagology in Great Britain; they met under the chairmanship of J. Mackenzie Brown, who spoke on the future of oto-laryngology, and their centennial address was delivered by R. A. Fenton.

R. Debré, of Paris, lectured to the *pediatric section* on the deleterious results of overdosage of vitamin D. during infancy; E. P. Copeland gave the centennial address; and other subjects ranged from the management of tick typhus in childhood to rheumatic fever.

The *section on experimental medicine and therapeutics* received contributions which may eventually affect the practice of medicine in many specialties. R. A. Woodbury and his colleagues discussed asymatrine hydrobromide in the treatment of gastro-enteric hypermotility, and L. O. Jacobson the use of nitrogen mustards in the treatment of disease. Jacobson has found that the course of acute leukæmia and multiple myeloma is unaffected by these drugs, but that significant clinical remissions are produced in Hodgkin's disease, lymphosarcoma, chronic lymphatic and myelogenous leukæmia, and polycythæmia rubra vera. I. Snapper, in a paper on stilbamidine in the treatment of multiple myeloma, reported that whilst the drug might relieve pain it did not cure the disease. J. Luetscher and W. T. Longcope discussed B.A.L. therapy in arsenic and mercury poisoning, and F. M. Rackemann the use of anti-histamine drugs. C. Heymans, of Ghent, the foreign guest, contributed a paper on blood-pressure homeostasis and circulatory failure. The chairman, C. A. Dragstedt, spoke on idiosyncrasy to drugs.

In the *section on pathology and physiology*, besides a symposium on the present status of cancer research, papers were contributed by J. J. Moore, the chairman, on the practice of pathology; G. Liljestrand, of Stockholm, on regulation of the arterial pulmonary pressure; H. T. Karsner (centennial address); E. W. Schultz on viruses and virus diseases; and H. J. Corper and M. L. Cohn on various phases of the use of streptomycin in tuberculosis.

T. Alajouanine, of Paris, was the foreign guest in the *section on nervous and mental diseases*. S. Cobb gave the centennial address, and R. P. Mackay, the chairman, spoke on the Neurologist Looks at Discipline.

O. S. Ormsby delivered the centennial address to the *section on dermatology and syphilology*, and was followed by the foreign guest, R. M. B. MacKenna, who spoke on the international outlook in dermatology. The chairman, N. P. Anderson, in a paper on cysts, sinuses, and fistulas, did much to make simple a subject which is complicated in many books by traditional beliefs and muddled thinking. H. E. Michelson spoke on sarcoidosis, and amongst many other papers that by H. J. Templeton, C. J. Lunsford, and H. V. Allington on autosensitisation dermatitis may be referred to as confirming views first suggested by Whitfield in England.

The work of the *section on preventive and industrial medicine and public health* was made particularly interesting by a paper from S. Forssman, of Sweden, on comparative practices in industrial medicine in Sweden and in the United States, and by a symposium on the question of how scientific proof could be attained in workmen's compensation controversy.

In the *urological section* W. J. Kolff, of Holland, spoke on the artificial kidney (his apparatus was demonstrated in the scientific exhibition); G. Carroll, the chairman, discussed *Ps. aeruginosa* (*pyocyanea*) and related bacillary infections of the urinary tract; and F. S. Patch, of Montreal, the foreign guest, read a paper on epithelial metaplasia of the urinary tract.

The *section on orthopedics* was addressed by J. Valls, of Buenos Aires, on aspiration biopsy in the diagnosis of lesions of the vertebral bodies; by L. F. Bush and C. Z. Garber, who discussed storage in the bone-banks by "deep freeze" methods; and by E. W. Ryerson, who gave the centennial address. H. J. Seddon, of Oxford, contributed a paper on nerve lesions complicating certain closed bone injuries.

The *section on gastro-enterology and proctology* held a symposium on the pancreas, another on ulcerative colitis, and a third on gastritis and gastric neoplasms. The chairman, M. S. Kleckner, spoke on proctologic surgery of the large bowel; J. A. Bargen gave the centennial address; and J. McMichael, of London, the foreign guest, reviewed clinical and biochemical problems of liver disease as revealed by systematic biopsy studies.

G. W. Holmes gave the centennial address to the *section on radiology*; G. E. Gomez, of Colombia, South America, was the foreign guest and spoke on cardiac hypertrophy in residents of high altitudes.

The *section on anesthesiology*, under the chairmanship of C. F. McCuskey, considered many topics, and were addressed by A. R. Hunter, of Manchester, the foreign guest, on anæsthesia for operations within the vertebral canal.

E. Ashworth Underwood, of London, addressed the *section on miscellaneous topics* on the spread of the public-health movement, 1847–1947; and D. Y. Solandt, of Toronto, spoke on the relationship of physical medicine to industrial medicine; both were foreign guests.

General scientific meetings were held on June 9 and 10. G. W. Pickering, of London, addressed the first of these on the subject of hypertensive encephalopathy, and also took part in a panel discussion on the modern management of heart disease. H. J. Seddon gave a paper on nerve grafting in the limbs, and took part in a panel discussion on emergency surgery. Sir Howard Florey, F.R.S., spoke on new antibiotic agents and later discussed the development of bacterial resistance to antibiotics.

The foreign guests were royally entertained. Not only were their creature comforts tended in the spacious rooms of their hotels, but they were wined and dined with heart-warming cordiality by private groups, societies, and official bodies. On June 10, before an audience said to number 6000, they heard a concert given by the Philadelphia Festival Orchestra, in which a surprise item was a military march written by the new president of the American Medical Association, Dr. E. L. Bortz; they also watched the installation of Dr. Bortz, who read a most able paper on the work, aspirations, and policy of the association; and they were then individually introduced to the audience. The guests were awarded honorary fellowship of the association. On June 12 they dined with the Alpha Omega Alpha Honour Society, of which they were made honorary members; as the society has a limited entrance this is a greatly prized distinction. Later in the same evening, at the president's reception and ball, they had the pleasure of greeting the president's guests, shaking hands with hundreds of representatives of the American medical profession, their wives, and their families.

Doubtless some other convention is now being held in Atlantic City; doubtless the curving waves caress the vigorous bodies of other young Americans—honeymoon couples, the young, the middle-aged. The scientific exhibits and the technical exhibits are no doubt away in crates and cases. Medical controver longer echo through the meeting rooms. As Atlantic City is concerned, the Medical Conven over. But in the minds of those who attended will remain the memories of friendships made and re of hospitality on a scale seldom experienced, knowledge gained.

Reconstruction

LOCAL GOVERNMENT IN TRANSITIO

Sir RONALD DAVISON

OUR system of local government dates back to 1 and everyone agrees that it is in need of a drastic haul. Reform has been in the air for a long time; should now come down to earth. One part of the was entrusted in 1945 to the Local Government Bo Commission which is now beginning to show its and has published its first report.[1]

I do not envy Sir Malcolm Trustram Eve and five colleagues; they have a difficult job in re the jig-saw of areas. Their mere existence as a mission has aroused the worst passions of local coun and their chief officers. There is apprehension cupidity at all four levels of the hierarchy: the boro are preparing for war on their county councils, w urban and rural district councils are afraid of the cou boroughs and are jealous of one another. Money is the root of most of this—i.e., the desire to enl rateable values and keep rates down—but civic p comes in too. Most councillors at all four levels themselves ruling over a larger and nobler domain, they dislike the thought of being subordinated or redu in area. The great county boroughs (50,000 to 500, population) are the most aggressive; some of th have not even shrunk from asking that their fut boundaries should be enlarged eightfold or tenfold. face of all this, the commissioners are treading cautiou for they know that as soon as they make actual alterati of status and area they will have to face very str objections.

Civic patriotism is a curious emotion; I have he of one fervent Lancastrian who swore that he wo quit his home and his village if it was transferred the Yorkshire County Council: "I couldn't possi stand up to the Yorkshire winters," he said. In own district of Oxfordshire the urban district counci spending £600 on a plan for encroaching on its surrou ings, including my home, but the rural district cou is preparing to die in the last ditch rather than surren any territory. In my opinion it is the council rather than their constituents who feel all this bittern

One of the wise suggestions of the commission is t we should now get rid of this complicated hierar from non-county boroughs down to rural district counc In all of them the major functions, like education, run over their heads by the county councils. Ther nowadays very little difference between the powers duties and rateable values of non-county boroug urban districts, and rural districts. It is the ru authorities that have caught up on the small tow and henceforth, say the commissioners, all small town a county district councils should have the same sta and be known by a common title. Stimulated by n tasks in housing and coming duties in respect of th local hospitals under the National Health Service, county councils plus district councils and their sta are very much alive. This two-tier system of gove ment covers 97% of the area of England and Wales a 60% of the population. It is therefore at least important that any new reforms should work out w in these sectors of Britain as that they should do so the great county boroughs.

THE COUNTY BOROUGHS

At present it is the big cities and conurbations th get all the limelight; and they certainly get it in t

---

1. See *Lancet*, May 3, p. 617.

ndary Commission's report. But strange to say, en our modern system of municipal government was structed in 1888, it was the new county councils—luding the mighty L.C.C.—that were to be the ured instrument of government. At that time, I ieve, only 6 of the largest British cities, including nchester, were held to qualify for county borough us with powers and duties equivalent to a county ncil. Yet today there are 83 county-borough coun-s, and 80 of these have demanded extensions of area. ere may also be 35 new all-purpose county boroughs, king 118 in all. The claim is that the county borough s proved to be the most convenient and efficient of forms of municipal administration, but that nearly of them are sadly overcrowded and have long over-t their borders, so that they want to rehouse or apture a large surplus population outside their present al boundaries, usually in a county district. It certainly ms wrong that an urban agglomeration should be titioned under various minor authorities; and still se that large conurbations, such as those centring on nchester, should be created into a solid block of parate county boroughs, ten or a dozen in number. n the other hand, what is to happen to the depleted nty councils when their richest districts are taken m them? In Lancashire the county's rateable value uld be reduced by two-thirds.

The commissioners offer various solutions, but un-ubtedly the one which attracts them most is the new ea which has emanated from the South Lancashire cities. he Manchester plan is to create a new kind of county uncil, rather like the L.C.C., embracing all the urban eas and working on the two-tier principle. All major rvices like education and highways would fall to the rong central council, while enough powers and duties ould be left to the individual boroughs to keep them ely and democratic—again very much like London th its county council and its borough councils.

CHANGES AND CHANCES

All these new plans for urban and rural administration re tentative at present. What are the chances of their eing realised?

Some of the adumbrated changes will call for new gislation of a rather thorny kind, and I cannot see e present Government seeking such a troublesome ddition to their overcrowded programme. Then there s vital interrelation between all this and the emerging licies of the Ministry of Town and Country Planning. ew trunk roads, new housing, and the relocation of dustry—all these will give rise to new boundary roblems and will affect the status of certain local uthorities. What about the schemes for new towns at tevenage, Crawley, and elsewhere? These are a big dventure and novelty, each with (in time) 50,000 habitants decanted from Croydon, Mitcham, and such-ke boroughs. The creation of new communities on e lines of Welwyn may become fashionable in the rth as well as in the south.

Finally, money being the king-pin in this as in ther reform projects, there are now to be substantial odifications of the block grants from the Treasury. he Boundary Commission should, of course, be able to evise their decisions, but they have not yet got power o do so under an interval of ten years. Altogether t looks as if "interim reforms" were going to be he order of the day for some years to come.

But something more vital than changes of boundaries nd statutory powers will be needed before our local overnment is really reformed. We need a far more ctive civic life among the citizens—instead of leaving bcal affairs to small exclusive groups of councillors or ould-be councillors and their friends. I lived in London uring the 1930's and the war, and the only times I ad any real contact with my borough council and mayor were, first, when we started occupation centres or the unemployed in 1934, and, second, when we were ll enrolled as air-raid wardens or firewatchers. It seems lmost as if nothing but danger and disaster will stir up the civic consciousness of the citizens of this country as a whole. Active democracy in the neighbourhood and street is even more necessary in times like these.

Modern Care of Old People

V

INDEPENDENT DWELLINGS

MANY old people, especially women, are well enough to look after themselves, and like to keep their independence. Some local authorities are providing for these by including two-roomed bungalows or flats in their new housing estates; and some almshouses offer very much the same sort of accommodation.

Bungalows

In Trowbridge, Wiltshire, the urban district council has three housing estates, two already complete and one now in the building; and in each of these provision has been made for old people. In the first estate, which dates from 1935, there are 10 bungalows among the 154 houses, and in the second 20 bungalows among 214 houses. The third estate will have 144 houses with 12 bungalows among them. It is interesting to see how practical experience over the years has led the council to modify the design and equipment of these small neat homes.

In the first estate the semi-detached bungalows contain a living-room, bedroom, kitchen-scullery, cupboard-larder, bathroom, indoor water-closet, and indoor coal-house. The front door, set back in a porch, opens directly into the living-room, into which the kitchen and bedroom doors also open. Though the fireplace is at the opposite end of the room from these three doors, the arrangement is bound to be a little draughty. In some of the living-rooms there is a cooking-range, in others an ordinary open fireplace; in either case there is also a gas-cooker in the kitchen and a gas-copper in the bathroom, which besides being used for household washing will feed the bath with hot water when required. There is no direct hot-tap to the sink, but the copper is easily accessible from the kitchen, and a kettle can be boiled quickly on the cooker or the range. The bedroom has its own fireplace. Coals must be delivered to the coal-house through the back door (a door closes off the kitchen). There is little room for the storage of bulky objects—such as tin baths, washing-boards, and the like—which are therefore liable to find their way into the bath. Each bungalow has a fair-sized garden-plot at the back—perhaps on the whole rather too large for the average old person to manage, though most of the plots are well kept, either by the resident or a son or friend, and used for growing vegetables. These early bungalows were placed at corner sites in the housing estate, set quietly back from the other houses—an arrangement which proved to be a mistake: the old people like to watch who comes and goes up the street, and complain if they are out of eyeshot.

In the estate now being built the small drawbacks of the earlier bungalows have been corrected. The bungalows have been built in terraces, facing a main road, though set back behind wide grass verges. The old people can thus watch what goes on without being directly on top of the traffic. The garden-plots are smaller, better suited to their strength. A porch shelters the front door of each bungalow, and helps to shut off draughts, while the bedroom door, instead of opening into the living-room, opens into the kitchen. Thanks to a special type of hearth, the living-room fire heats water, and the hot-pipe carrying this to the kitchen and bathroom warms an airing cupboard on the way. The kitchen and bathroom still have both a gas-cooker and gas-copper, so the resident is not obliged to light a fire in order to get water for the wash-tub. The coal-house can be fed through an outside shutter, the coals being shovelled into the scuttle through a hatch inside the house. The larder is to be of brick instead of wood, and each bungalow has a roomy brick storehouse alongside, which in the far future might be converted into that favourite convenience, an outside wash-house.

The occupants of bungalows pay a rent of 2*s.* 6*d.* a week, which also covers rates. They are mostly women, but in a few bungalows old couples are living comfortably. Sometimes the council has found it possible to move a widow or an old couple into one of the bungalows from a house which has become too large for them. In one case a three-bedroom house vacated by a widow received instead a family of six—four children and their parents—who had been living in one room.

It has not so far been possible to provide any special care for these old people when they fall ill: they have to depend on friendly neighbours and the district nurse, being transferred to the infirmary when things go badly wrong. They are fortunate however in the human friendly interest taken in them by the local authority's officers, who, if hospital treatment becomes necessary, go round and reassure them about the sanctity of their homes in their absence, and who come in and lend a hand, until the expert arrives, with such domestic disasters as burst pipes and smoky chimneys. Such estates probably need a resident nurse and an adequate home-helps scheme; and this is under consideration.

Almshouses

Though modern almshouses are often structurally excellent, it is not often possible to equip them on the same scale as the municipal bungalows just described. Some good examples seen at Devizes serve to demonstrate this. A group of 12, 8 of which were built in 1910 and 4 in 1925, are administered by St. Mary's Church and Poor Lands Charity. Set round a pleasant well-kept lawn they are neat and strong little cottages of red brick. In the porch of every house stands a stout wooden garden seat, capable of taking two; and from one side of this porch the door opens directly into a living-room which is connected by an arch, usually curtained, with a small bedroom-recess. The hearth is fitted with a cooking-range, and there is also a gas-cooker in the small kitchen-scullery at the back. There are no bathrooms in these houses, but each has its indoor water-closet and coal-house, and there is a good brick larder and a roomy built-in dresser. The back door opens on to a tiny strip of asphalt which serves as an airing ground to the cottages backing on to it. Those residents who like gardening have a share in maintaining the borders, and there are good patches of kitchen-garden in two corners. The residents pay no rent, and are given free coal and wood in winter; they seem comfortable and satisfied. When ill they are treated by their own doctor.

Close to this community is another group of almshouses, belonging to the Devizes Municipal Charities, built on the same plan, and differing in only small particulars of equipment: the bench in the porch, for example, is missing, and instead of a range in the living-room there is an open fire with an oven above it—not a very satisfactory affair for the cook, since the heat, it seems, is ill distributed; the gas-cooker in the kitchen makes this of little account, however. These occupants, too, live rent-free, and seem well pleased with the convenience of their homes.

Dr. Frederick Hall, M.O.H. of Lancashire since 1936, has been appointed president of the Society of Medical Officers of Health.

Major-General Raymond W. Bliss has been appointed surgeon-general of the U.S. Army in succession to Major-General Norman Kirk, who is retiring. During the late war General Bliss acted as military observer in London, and later made extensive tours of the Pacific areas. He was an observer at the atom bomb tests at Bikini.

In England Now

A Running Commentary by Peripatetic Correspo

THE near approach of Henley and the sight of
boys rowing made me wonder whether I would
son to a rowing school. When I was at the uni
I enjoyed rowing tremendously, and I do not think
is anything to compare with the thrill of stro
well-balanced eight in a race at Henley—the
before the gun goes, the spring off the stretcher in
short first stroke, the quick second, then the long
with the crew getting into their stride. The feel
that slim shell racing over the water is rather like
where you speed down the mountainside on two
of board, but it is greater because you are one of a
and a team which answers to your every thought, spur
with that desperate ten or lengthening out to hold
other crew while they spurt. It was all very marvell
but there were also the dreary days of practice throu
the winter, especially those Mondays when nothing
right and the coach was unsparing.

Now rugby, on the other hand, gave pleasure
every game, even an ordinary game on a dull, wet
and cup finals can be very thrilling, so I would like
son to play rugby and to row; but rowing takes
one's whole time, and a general education in all sp
should come first, before there is any question of tak
up a specialty. The same with shooting—it was
fun shooting for the Armitage inter-hospital cup on
four Wednesdays in June, but did the "possible"
600 yards make up for never once having seen
Derby, which in those days was always run on
Wednesday?

Looking back on it, I think a little of everythi
you fancy does you most good.

* * *

It is extraordinary what excuses I can find for
having my daily dip while on holiday. I don't kn
about the currents round the Scillies; I must find
softer rock to undress on; after all it's only June
it's two hours earlier than the clocks say; I'm sure
wrong to bathe so soon after breakfast; the water
be warm in another hour; heavens, it's one o'clo
and if we don't go back now we'll be late for lun
and there's certain to be new potatoes and probab
cream. But tomorrow I really will go in.

* * *

A colleague of ours who is an expert in the breedi
of pure-strain mice has recently been transferred
other duties. After years of careful expert work
had produced a near-perfect strain, but his love of th
perfection was so great that he flatly refused to all
them to be mated.

* * *

Having for six years coaxed patients into undergoi
insulin therapy for the good of their health, I thoug
I would try it myself for fun, just to see what it f
like. I started off much too casually, reckoning
taking the customary three injections of ten units befo
meals, and had my first injection administered by
sister half an hour before breakfast.

It stung like a hornet, and for a good twenty-fi
seconds I was clenching my teeth and stamping round
small circles before it wore off. Breakfast was eat
without any undue enthusiasm, and I wondered if a
subsequent injections were going to be as painfull
ineffectual. Two and a half hours later, however, whe
self-imprisoned in the darkroom where I had just place
a couple of X-ray plates in the developer, I came ove
most peculiar. All my limbs quivered tensely as if
had just driven 100 miles flat out in a small car;
broke into a cold sweat and was filled with apprehensio
growing almost to panic. It got worse. The slow
moving hand of the luminous clock told me that m
X-ray plates had the choice of being somewhat unde
developed or—if I passed right out—of being utterl
ruined. The latter would apply also to the darkroo
door when someone eventually noted my absence fro
circulation. I made a choice I have never regretted

It is evident from table I that the modified test is much more sensitive than the standard Wassermann, being in fact comparable to the standard Kahn.[5] In the smaller series of cases treated with 'Mapharside' the difference between the results with the modified Wassermann and the standard Kahn are not statistically significant. Since the mapharside course was intensive, lasting on the average 30 days, it is reasonable to suppose that similar results would be obtained in patients treated intensively with penicillin. (I was not in a position to do Wassermann tests when penicillin therapy was introduced for syphilis.)

From table II it may be seen that not only is there an increase in the number of reactive sera detected when the modified Wassermann test is used but also in the number of agreements with the Kahn test. Further, in the cases treated with arsenic and bismuth, the number of sera which gave a positive Kahn reaction but a negative modified Wassermann was balanced by a similar number in which the reverse held. (The results from the smaller number of mapharside-treated cases show a similar trend.)

The reasons for these divergences are not always clear but may include the following:

1. Slight day-by-day variation in the sensitivity of the tests are inevitable in a complex biological reaction, such as the Wassermann, when carried out under routine conditions, and differences in the fixability of different samples of complement are a potent cause of such variation. The Kahn test is influenced, among other conditions, by the laboratory temperature; both the sensitivity and the specificity of the test are lessened by air temperatures lower than 21°C, which are usual in British laboratories.
2. Subjective errors which are due to the difficulty of maintaining over a period of time a constant assessment of the strength of minimal reactions (both the Kahn and the Wassermann show a more or less continuous change in intensity from positive to negative).
3. Neither test is strictly quantitative: the Wassermann because of the impossibility of measuring slight changes in complement activity at complete hæmolysis or complete inhibition of hæmolysis,[6] and the Kahn because of the high lipoid content of the antigen (added to render the test more sensitive) so that in weaker reactions a disproportionately large amount of the precipitate consists of lipoid.[7] In view of this lack of a linear relationship between strength of reaction and antibody content, it is not surprising that the results from the two tests do not always tally when tested in parallel.

It would, therefore, appear an advantage to carry out a sensitive complement-fixation test in addition to a satisfactory precipitation technique such as the standard Kahn, not only for their differing intrinsic ranges of sensitivity but also to compensate for any possible daily variation.

The use of strictly quantitative tests—e.g., the Wassermann reaction based on readings at 50% hæmolysis and the micro-estimation of antibody nitrogen in the specific precipitation—would probably record a parallel drop in reactivity as a result of treatment and thus indicate the essential oneness of the antibody concerned.

Liverpool. A. O. T. VAUGHAN.

BLOOD ENZYMES AND ACTIVITY OF PENICILLIN ESTERS

SIR,—The observations of Dr. Ungar (March 15) on the presence of penicillin-esterase in the blood of mice and rats, and its absence in the blood of man and the rabbit, can perhaps be related to the earlier classification of mammals into blood-maltase-positive and blood-maltase-negative groups.[8] Contrary to expectations, the similarity breaks down for the guineapig, which is a blood-maltase-negative animal (Compton) and a blood-penicillin-esterase-positive animal (Ungar). When one turns to the classification of Stedman, Stedman, and White of animal bloods in terms of positive and negative choline-esterase content, the findings are for the most part reversed: man bel their blood-positive group, as does also the while the rabbit, the rat, and to all intents the belong to their negative group. The rabbit's is negative on all three classifications.

How are these facts to be interpreted and reco The conventional answer is that they are exp of the varying enzymic make-up of the respectiv the chemical constitutions of the several substrates envisaged as constant.

These data suggest other possibly more useful m tions of the penicillin molecule.

Alexandria, Egypt. ARTHUR ÇO.

DIPHTHERIA IMMUNISATION

SIR,—These notes, referring to a medical st now aged 22 years, are of some interest. The v events are narrated in chronological order.

Nov. 9, 1945, primary Schick test positive ++.

First Course.—Nov. 16, given T.A.F. 0·5 c.cm. Dec. 5, 1 c.cm. Dec. 12, T.A.F. 1 c.cm. Feb. 2, 1946, T.A.F. 1 c

Second Course.—Dec. 3, 1946, Schick test positive. T.A.F. 0·5 c.cm. Dec. 17, T.A.F. 1 c.cm. Feb. 2, 1947, test positive. Feb. 18, Schick test positive. The t repeated to exclude pseudo reaction as control hac omitted on previous test. Antitoxin content of blood le 1/1000 unit per c.cm.

Third Course.—Feb. 25, A.P.T. 0·1 c.cm. March 3, 0·5 c.cm. April 1, Schick test negative. Antitoxin con blood 1/10 unit per c.cm.

The interesting features of this case are: (1) the to produce a negative Schick reaction with a con tively large amount of T.A.F. (5 c.cm.) plus the stin action of three Schick tests; (2) the rapid ap response to a relatively small amount of A.P.T. (0·6 as evidenced by the development of a negative reaction within three weeks and a considerable in in the antitoxin content of the blood; and (similarity between this case and another prev reported by me[1] in which there was a persistent l response to T.A.F., followed by a rapid conversion 0·6 c.cm. of A.P.T.

I am indebted to Miss M. Barr, M.SC., of the We Physiological Research Laboratories, for carrying ou necessary titrations.

City Hall, Cork. Medical Officer of He

EMPIRICAL TESTS OF LIVER FUNCTIO

SIR,—Having worked on serum-proteins,[2] I was interested in the article by Dr. Maizels in your iss Sept. 28, 1946 (p. 451). I have estimated, in more tha cases of endocrine, liver, or hæmopoietic disease total and partial concentrations and the water-bi power of the serum-proteins. The water-binding p was estimated as the colloid pressure exerted by 1 g 100 c.cm. of the actual albumin-globulin mixture i serum. The correlation between this reduced c pressure (R.C.P.) and the concentration of the se proteins can be expressed mathematically. My fin were compared with those in more than 100 no controls.

I agree with Dr. Maizels that a lowering of the alb globulin ratio is less common in obstructive jau than in parenchymatous liver damage, but this good only in the first weeks, and sometimes only first few days, of all pathological conditions associ with jaundice. In the later stages of obstructive jaur the ratio decreases; hence in a jaundice 3 or 4 w old quantitative protein estimations are not a r criterion in the differential diagnosis. Moreover, fact that physiological values of total and partial pro concentrations vary within a fairly wide range les still further the diagnostic value of changes in the ratio.

this country. The possibilities of ergothioneine being used clinically[1] and of its being free from toxicity were of great interest to clinicians informed of the initial experimental work. In the long view, however, much was expected of radioactive iodine by mouth in thyrotoxicosis; and I certainly saw some impressive results.

London, W.1. S. L. SIMPSON.

VENEREAL DISEASE IN BRITISH WEST AFRICA

SIR,—I was interested in your annotation of May 17. My own experience is limited to Nigeria, where I served with the R.A.M.C. for eighteen months. During that time (in 1945–46), it was the policy of the higher authorities to board native troops out of the Army if they were proved sufferers from "chronic gonorrhœa." This soon became widely known and was exploited, mainly by the more educated who wished to get out of the Army and into a civilian job before their brothers returned from Burma to flood the labour market.

Many cases of gonorrhœa then presented themselves for treatment and were admitted to hospital. All denied that it was their first attack and they invariably gave a history of anything from one to ten attacks. Few of them knew their own ages, but the approximate date of the first attack gave one a fair idea of how old they were. They were treated with sulphonamides, to which they were invariably resistant, then by hyperpyrexia, and finally with penicillin. At the end of treatment they usually had as much urethral discharge as on admission. Although no definite proof was ever obtained I am convinced that whenever a test-of-cure smear was to be taken from a patient who had undergone treatment he would reinfect himself from another patient more recently admitted.

Getting these people "V.D.-conscious" is going to be a very considerable task. It is impossible to promote this consciousness among the uneducated; in West Africa, therefore, the standard of general education must be greatly improved before any hope can be entertained of conquering the V.D. problem.

LIKITA.

CLIMATE AND RHEUMATISM

SIR,—During the last years of the late war I was M.O. of the first-aid post in the Chislehurst caves. These are huge artificial excavations in chalk and consist of two parts, one of which is damp and rather warm, the other damp and cool.

Though this shelter was occupied nightly for years by up to 14,000 people, and the first-aid post was frequented for medical treatment of minor ailments, I cannot remember a single person coming for treatment of rheumatism. Indeed people said they lost their rheumatism there.

I slept myself for several months in surroundings where the walls were dripping wet, and got neither colds nor symptoms of rheumatism. My 3-months-old baby also had no ill effects from sleeping underground in the dampness, though we were careful each time to take the bedding home and air it properly.

Leicester. G. FINKENSTEIN.

ESTIMATION OF VITAMIN C IN LEUCOCYTES

SIR,—In connexion with my paper of May 31 (p. 750) on the adaptation of Roe and Kuether's method to the estimation of vitamin C in leucocytes, I should explain that when I started my work in March, 1946, owing to inaccessibility of certain journals and abstracts I was obliged to rely on the latest available volumes of the *Quarterly Cumulative Index Medicus* for relevant references and I was unaware of recent or contemporary work of a similar character, apart from the original publications of Butler and Cushman (1940) and Roe and Kuether (1943). I can only assure Dr. Sinclair and Mr. Lloyd that the lapses they mention were unavoidable in the circumstances. I should also like to say that I employed the term "microprocedure" referring to the 15–25 mg. of the leucocyte sample and not to the blood-volume from which it was obtained.

London. P. C. CONSTANTINIDES.

CEREBRAL ANGIOMATA

SIR,—The report by Mr. Kidd and Dr. (May 31) of two cases of familial cerebral an most interesting.

The paper alludes to "the probability of tendency in the formation of some angiomata. suggest that such a condition has long been in the syndrome known as Rendu-Osler-Web or hereditary hæmorrhagic telangiectasia? I order angiomata may involve all tissues; an lesions and hæmorrhages, though not an essenti have been reported.

Unfortunately Kidd and Cumings do not whether angiomata elsewhere than in the b found or searched for, especially on the muc same applies to the family history: hæmorrh where than into the brain may be overlook attention is not paid to the possibility occurrence.

Namur, Belgium. G

ISAACS-LUDWIG ARTERIOLE

SIR,—In your issue of June 21 Dr. Barcla colleagues plead for the name of Isaacs to be with that of Ludwig in the designation of t vessel which is usually referred to as " arteriole." None will deny that the early tr of physiologists, Bowman, Isaacs, and Ludwig in the modern era of renal physiology. welcome the name of Isaacs, the American being coupled with that of Ludwig so as better the memory of an eminent physiologist whos less well known in Europe; for, while it is fairly appreciated that the work of these three leaders began independently, it may not be realised tha work (1857) preceded the classic maceration-d of Henle (1862) and Schweigger-Seidel (1865) seems a doubtful honour to have as a memor anomalous vessel of no physiological significan

None will deny that this arteriole does exi since so much attention has been attached to from debate concerning its existence and now it tion, it is more than ever necessary to reiterat is a rare anomalous arteriole of no physiologic cance. By way of requiem may I quote description as it is contained in the Sydenha of Stricher's *Human and Comparative Histolo* vol. II, p. 89)?

> ". . . a *few* of these very numerous vasa before they reach the spherical extremity of th tubule, give off a very fine branch, that im breaks up into capillaries, through which the bl into the capillary plexus investing the urinar Every vas afferens alike, whether it has previo off branches, or remained undivided, turns to o spherical dilatations of the urinary tubule, and the wall opposite to the commencement of the canal or neck."

May I repeat that Ludwig fully understood Bowman (1842), that "All the blood of the ren (with the exception of a small quantity distri the capsule, surrounding fat, and the coats of t vessels) enters the capillary tufts of the bodies" in relation to the special function of f and that Ludwig's was the brilliant conceptio filtration-reabsorption theory of urine formation.

In recent years, detailed studies of the renal ci in animals, in normal and pathological conditio in the human kidney in like diseased states, lea confirm that the renal circulation is primarily glo

Parliament

ON THE FLOOR OF THE HOUSE

:hancellor of the Exchequer was able this week some concessions to taxpayers. The exemption ances for Territorial training from income-tax arious kinds of gas and electric cooking utensils ing cooking stoves—from purchase-tax is . The plea for the exemption of medicines and and surgical appliances put forward by Mr. was not accepted because to do so would lose sury £9 million; but the Financial Secretary out that there is a long list of essential and rugs which are exempt from taxation, and so y surgical necessities, including instruments, surgical dressings, bandages, and hospital . The plea for the exemption of toothbrushes by the roadside despite the touching plea by Bromley-Davenport: "Surely social democracy anced sufficiently . . . for toothbrushes to be as a universal necessity rather than as a luxury idle rich." Another exemption from taxation stbins, but here the question arose whether ise should cater for those "dustbin snobs" ins have *lids*. Anyway, the Chancellor impartended his blessing to all classes of dustbin.

esday was devoted to Scottish Housing, and ide the Sassenach who puts his nose into a lebate. But when it came to the Opposition a vote against the Government to a division enachs public-spiritedly came forward in support.

housing has been and is worse than English, o the present about 8500 permanent and 17,000 ry houses have been built, and the temporary is popular house in Glasgow. So even if Scotland ing all it wants to do it is still getting along.

finance and housing to foreign affairs is not big jump as it sounds. Mr. Bevin, fresh from to Paris to consult the French government "Marshall plan"—which is not a plan but a on of financial coöperation—hoped to receive ws before he made his speech at the end of the

The question Europe is asking is—are there ngs to the Marshall offer? Is the U.S.A. content improve economic conditions generally or must nform to rules laid down by the U.S.A.? The re then that some general coöperation will come he Marshall proposals—but there may be a lot gling about the details.

MEDICUS, M.P.

FROM THE PRESS GALLERY

Purchase-tax on Drugs

he *committee stage of the Finance Bill* in the of Commons on June 17 Mr. H. LINSTEAD moved endment remitting entirely purchase-tax from ies and medical and surgical appliances. At drugs and medicines manufactured or prepared, han essential drugs "of an exceptionally costly er," bore tax at $16^{2}/_{3}\%$ whether the medicines ought over the counter or prescribed by a and this, Mr. Linstead declared, had given anomalies. For example, a substance like n, chloroform, or bicarbonate of soda if in its ordinary form did not bear the tax, en prepared for medicinal use the purchaser had the tax. Again, a drug such as penicillin, which empted from the tax by a Treasury order at a hen it was exceptionally costly, was still tax-free ter the cost had been reduced, while streptomycin, had not been added to the order because it was ew, was still bearing a substantial tax. Only ay he had heard of a patient who had paid in se-tax £23 for streptomycin.

Linstead urged that a purchase-tax on medicines ally a tax on sickness. The Government spokesould probably say that if it were merely a question licines prescribed by doctors, or medicines bought public, the Treasury would not be anxious to e tax retained, and attention might be drawn large trade in proprietary medicines. But surely if the proprietary medicine industry was suitable for control on grounds of public health, that control should be a direct one through the Ministry of Health and the accident of taxation should not be used. Even if the State was going to pay in a year or two for most of the medicines, and most of the expenditure of hospitals, it was still a clumsy device to go through the whole of an industry's machine in order to take money out of one pocket and put it in another.

Dr. S. JEGER said the two classes of people on whom the tax fell were doctors and chemists. Doctors, who were notoriously bad calculators, did not usually increase their fees by the amount of the purchase-tax, but chemists who dispensed or sold drugs over the counter could always pass on the tax to the customer. The consumption of medicine was far higher among the poorer people, and to that extent the purchase-tax on drugs and medicines was practically a working-class tax.

Mr. GLENVIL HALL, financial secretary to the Treasury, replied that to accede to Mr. Linstead's request would cost the revenue £9 million, and that showed how impossible it was for the Government to accept the amendment at this time. The tax fell mainly on ready-made preparations—pills and such-like—about which there could be a division of opinion. So far as these medicines and drugs were subject to tax it could not be said that they were essential to the life of the community. The vast bulk of medical and surgical appliances were already exempt from tax, and those which were not exempt could not be said to be particularly applicable to use in the hospitals or in the sick-room. If once a proprietary remedy for a particular disease like asthma was allowed to be sold free of tax the door was opened for claims on behalf of other proprietary remedies for the same complaint. The amendment was withdrawn.

Enforcement of the Penicillin Bill

On June 18 at the committee stage of the Bill the following new clause was moved by the Government:

> *The Pharmaceutical Society of Great Britain shall have* power to enforce the provisions of this Act, and for that purpose may employ the inspectors appointed by them under section 25 of the Pharmacy and Poisons Act, 1933, but nothing in this section shall be construed as authorising the society to institute proceedings in Scotland for any offence under this Act.

The duty of enforcing the provisions of the Pharmacy and Poisons Act, 1933, Mr. J. EDWARDS, parliamentary secretary to the Ministry of Health, explained, was placed on the Pharmaceutical Society, which for that purpose employs pharmacists as inspectors, and the society has a similar duty under the Pharmacy and Medicines Act, 1941. It therefore seemed reasonable that they should also be able to enforce the provisions of the *Penicillin Bill, though this, of course,* would be entirely without prejudice to the general duty of the police to enforce the law.

Venereal Disease in the Army

Replying to a question standing in Lord MORAN's name, Lord NATHAN gave the following quarterly rates for venereal disease in the Army.

QUARTERLY RATES PER 1000 STRENGTH: JANUARY, 1946 TO MARCH, 1947

	1946				1947
	1st	2nd	3rd	4th	1st
United Kingdom ..	7·7	8·7	9·6	6·8	5·3
B.A.O.R.	30·4	41·3	44·6	41·8	30·0
C.M.F.	33·3	39·5	35·6	31·5	22·8*
M.E.L.F.	4·1	9·4	9·4	7·6	6·3*
S.E.A.L.F.	37·6	37·2	37·2	32·0	31·2*
B.C.O.F.	—	—	59·6†	102·6	61·9*

* Quarterly rates based on January-February only.
† Quarterly rates based on August-September only.

QUESTION TIME

Streptomycin Supplies

Lieut.-Commander G. BRAITHWAITE asked the Minister of Health whether he was satisfied that adequate supplies of streptomycin were reaching this country for the use of hospitals and general practitioners.—Mr. A. BEVAN replied: The merits of this drug have not yet been established and it is still under clinical trial by the Medical Research Council. The only supplies which have been obtained by the Government are for the purpose of these trials. Commander BRAITHWAITE: In view of the increasing broadcast appeals for streptomycin and in view of the fact that it is apparently readily obtainable from drug stores in the United States, may I ask whether the shortage here is in any way due to our dollar difficulties, or is it through opposition in high medical quarters?—Mr. BEVAN: There is no restriction on the dollar side to the purchase of whatever amount of streptomycin is necessary for the tests, but in view of the fact that this drug has not yet been proved, I am very glad to know that it cannot be obtained in drug stores in this country.

Mr. W. SHEPHERD: As these appeals cause a great deal of alarm, cannot the Minister do something to stop them?—Mr. BEVAN: I have made an announcement in the House deploring these appeals for drugs which are not properly tested beforehand. I regret very much that the B.B.C. is giving facilities for these appeals. Dr. S. TAYLOR: Is the Minister aware that in the United States the sale of streptomycin is not through drug stores and that it is controlled by the National Control Council there as it is here?

Certification of the Insane

Mr. G. WALLACE asked the Minister if he would review, with a view to early amendment, the regulations regarding the certification of the insane.—Mr. BEVAN replied: As soon as opportunity permits, it is intended to undertake a restatement of the law relating to mental treatment.

Mr. S. S. AWBERY: Is the Minister aware that a person who has been certified finds it almost impossible to get release even when he has recovered from his sickness, and that even after the visiting magistrates have recommended release it takes six months before the patient is released from the institution, and then only with a six months' licence?—Mr. BEVAN: I am afraid I cannot accept what appears on the face of the supplementary question, and I would warn hon. Members that this is a very difficult thing indeed, and they ought not to take things at their face value, because there is such pressure on institutions for additional accommodation that I cannot believe that superintendents keep anybody there longer than is necessary.

Institutions for Mental Defectives

Mr. WALLACE asked the Minister if he would set up a committee of inquiry into the conduct and administration of institutions and hospitals for the mentally deficient.—Mr. BEVAN replied: These institutions and hospitals (which for the most part will be taken over in the new health service) are subject to regular inspection, and I am not aware of the necessity for setting up a committee of inquiry.

Sir RALPH GLYN: In view of the overcrowding now existing in a great many of these places, and the difficulty of building, will the Minister have a survey made to show the bad effect which this overcrowding has on the patient?—Mr. BEVAN: I am well aware of that, and I think hon. Members will know that even if we had additional buildings, we would not be able to make use of them, because we have not enough staff. When the new health service is in operation, I hope we shall be able to make far better use of existing accommodation.

Mr. D. L. LIPSON: In view of the general concern over this matter, will the Minister give an assurance to the House that the report which he has received from his inspectors will not justify any serious cause for anxiety in regard to the conditions in the majority of these institutions?—Mr. BEVAN: I am well aware that conditions in these institutions are not anything like as good as we would like them to be, and it is because of the overcrowding and the lack of nursing and domestic staff. We are doing our utmost to build up the staffs and we are having some success.

Report on Proprietary Medicines

Mr. C. N. SHAWCROSS asked the Minister whether he had considered the report on the subject of proprietary medicines submitted to him by the Pharmaceutical Society of Great Britain; and what steps he proposed to take to implement the society's recommendations.—Mr. BEVAN replied: given the report preliminary consideration. The recommendation would involve legislation, for wh afraid there is no early prospect.—Mr. SHAWCRO not the Minister agree that this is a matter of far- importance which becomes ever more urgent with the of a national medical service?—Mr. BEVAN: I ag is of the utmost importance, but there are very large of matters of great importance that are also awaiting tion, and it is a question of priority. I can assure friend that it is always present in my mind.

Mr. L. J. SOLLEY: Can the Minister make this available to members?—Mr. BEVAN: I believe it is a document, and therefore I cannot promise to make able.—Mr. SOLLEY: Could not the Minister app society to ascertain whether they would object to the tion of the report so that members could study it in of the national interests involved?—Mr. BEVAN: certainly make inquiries.

Free Lavatory and Toilet Facilities

Mr. V. McENTEE asked the Minister if, as a m encouraging cleanliness and improving public health, he arrange to make a reasonable grant to local authorit provided, as a public service, the free use of lavat wash-basin facilities with soap and towels in publ veniences for men and women.—Mr. BEVAN replied no power to make such grants.

Mr. HEATHCOAT AMORY asked the Minister whether, interest of public hygiene, he would encourage local aut to extend the provision of washing facilities in public lav including free access to water and basins.—Mr. replied: It would not be appropriate at the present when the essential materials are in short supply, to local authorities to provide additional washing f in public conveniences. They already have full discre provide such facilities free of charge.

College for the Deaf

Mr. EDWARD EVANS asked the Minister of Education progress had been made in the provision of a county for deaf adolescents; and if he would make a state Mr. G. TOMLINSON replied: The Sheffield local edu authority has agreed to provide a boarding county col sufficient size to meet the needs of all deaf adolescents be the ages of 16 and 18.

Allowances for the Tuberculous

Mr. E. G. WILLIS asked the Minister of Health what the operation of the National Insurance Act would upon the tuberculosis allowances scheme.—Mr. JOHN ED replied: The increased sickness benefits payable unde Act will be available to the tuberculous in common with sick persons. The question of further financial help o lines of the present scheme is being considered in conn with the National Assistance Bill which is to be intro next session.

Meals for School-children

Mr. G. R. CHETWYND asked the Minister of Educati he would give the number of school-children receiving dinners, dinners on payment, and no dinners, respecti and the number of schools providing free dinners, dinne payment, and no dinners.—Mr. GEORGE TOMLINSON repl Last October there were, in round numbers, 340,000 chil in grant-aided primary and secondary schools who rece free dinners, 1,920,000 who had dinners on payment, $2^1/_2$ million who did not receive dinner at school. Din were being provided at over 24,000 out of 29,000 schoo departments, and it may be assumed that at practicall of these free dinners were available in case of need.

Food for Germany

Mr. PETER FREEMAN asked the Secretary of State Foreign Affairs what increased amounts of food had been allocated to Germany to meet the serious shorta and what is the present calorific value of the amount being actually received per head.—Mr. E. BEVIN repl A special emergency allocation of cereals, equivalent 137,000 tons of flour, will increase the expected arrival cereals for human consumption in the Combined Zones the equivalent of about 400,000 tons of flour in both J and July. The average daily caloric value of the ra actually available to normal consumers was slightly less th 1000 calories in May and is likely to remain at about t level in June.

invited to one of Howard Humphris's dinners was an event not easily forgotten. A gourmet (not a gourmand), he delighted in entertaining his friends with rare and delicate foods and wines. Equally at home on the Continent, he appeared to know where the most delicate and best cooked meals could be obtained."

Dr. Humphris married Miss Ethel Marion Hesketh, who survives him. He died at Bath on June 17.

DONALD JAMES MACKINTOSH

C.B., M.V.O., M.B., LL.D. GLASG.

Colonel D. J. Mackintosh, who died on June 12 at the age of 85, was medical superintendent of the Western Infirmary, Glasgow, from 1892 to 1937. During his long period of office he took a prominent part in hospital planning and earned an international reputation as an expert in design and equipment. A pioneer in the development of X-ray apparatus, he worked hard to establish radiology as a hospital department, and he made important contributions to the layout and equip*ment of operating-rooms.*

He qualified in medicine at the University of Glasgow in 1881, and after holding a resident post at the Glasgow Eye Infirmary joined the staff of Belvidere Fever Hospital. His career in hospital administration began with his appointment in 1890 to the Victoria Infirmary, of which he was the first medical superintendent, and two years later he became medical superintendent of the Western Infirmary. He was largely responsible for the organisation and equipment of the Scottish National Red Cross Hospital at Kroonstadt during the South African war, and when the Territorial Army was formed he became lieut.-colonel commanding the 3rd Scottish General Hospital. Later he was A.D.M.S. in the Lowland Division, and in 1914 he was appointed to supervise the organisation and administration of all military hospitals in the Glasgow area.

Mackintosh's capacity for organisation gave direction to his voluntary work. He was chairman of the council of the St. Andrew's Ambulance Association from 1911 until 1914 and he was made a vice-president in 1920. For many years he was vice-chairman of the General Nursing Council in Scotland as well as chairman of the Scottish board of the Royal College of Nursing. An original member of the British Hospitals Association, he was the first honorary secretary and afterwards chairman of the council. In 1929 he was appointed by the Secretary of State for Scotland to the Central Liaison Committee for Voluntary Hospitals, and he was invariably called upon to give expert evidence before any commission investigating hospital problems. The many hospitals which sought his advice at times of construction and reconstruction included the Glasgow Royal Infirmary, the General and Children's Hospitals at Nottingham, Falkirk and District Royal Infirmary, and North Staffordshire Royal Infirmary. He was also one of the most active members of the board of management of the Glasgow Royal Maternity and Women's Hospital. These services brought him many honours. He was a companion of the Order of the Bath, a member of the Victorian Order, and a knight of grace of the Order of St. John of Jerusalem. In 1912 the University of Glasgow conferred on him the honorary degree of LL.D., and he was also a deputy lieutenant of the county of the city of Glasgow.

"In the days when medical superintendents really governed," writes a colleague, "Colonel Mackintosh was recognised as a disciplinarian. His bark was ferocious. In making his way along the corridors of the Western *Infirmary he looked like a battleship escorted by a* flotilla of destroyers. He had an uncanny knack of discovery followed by the discomfiture of the law-breaker. It may be said that he lacked certain graces, and his exterior was undoubtedly formidable. Behind all this lay a Highland spirit, loyalties that were life-long, and as high standards for himself as he set for others. On looking back over the years thousands of residents and nurses will remember the super with kindliness and admiration, and few with rancour."

Dr. Mackintosh is survived by his wife and daughter. His son, Donald Mackintosh, was killed in action in France in 1917, and was posthumously awarded the Victoria Cross.

SIR ALMROTH WRIGHT

Prof. D. W. Carmalt-Jones writes from New
"I have heard privately of the death of S
Wright, but the journals with his obituary n
not yet arrived in this country. As an old
deeply in his debt, I should like to add my tr
memory at this long range, before it is too
will have been made of his career and of the ho
him, titular and academic, and of his servic
preventive and curative medicine, of his
intellect, his technical ingenuity and skill, h
trative gifts, his versatility, perhaps even of h
of his controversial vigour—maybe of his 'b
its suggestions of Mr. Dick's *Memorial.* On
however, is less well known and is probabl
recorded, but has always been to me most cha
and important, and that is his influence on his

"Provided one kept within the four corne
doctrines accepted there, the most outspoken
was prevalent and encouraged in the laborato
was generally expressed in the most un
language. Wright used to say: 'This lab. is a
as all the world ought to be.' It was nothing of
it was a benevolent despotism. The rule of
though it was never stated, was that the wo
day must be done in the day, and that by the
workers, not by the technicians. I write of fo
ago and the early days of the opsonic index,
main work was done at night. Things often we
a whole batch of slides had to be scrapped and
repeated. No-one ever thought of postponing
following day; we stayed on till the job was
the results entered up. It might be thought
that Wright was a martinet. Nothing of the
never heard him give an order; the work was
be done, and we should as soon have thought o
it unfinished as of going without our breakfasts.
who, without orders given, kept a team of yo
out of their beds till past midnight several times
and for years on end, had some remarkable qu

Public Health

The Mental-health Service

THE Minister of Health has announced t
functions of the Board of Control, other than
a quasi-judicial nature, are to be transferred
as from July 1. A mental-health division of the
of Health, to which the appropriate membe
officers of the board are transferred, has been esta

He has also sent to the appropriate bodies a
outlining the form which the proposals of local
authorities for administering their mental-health re
bilities should follow. These duties will invol
appointment of duly authorised officers who wi
the initial steps in providing care and treatm
persons suffering from mental illness. Former re
officers with experience in this work (which in
is to be divorced entirely from the poor-law) a
part-time use of psychiatric social workers, spec
authorised for this purpose, are recommended.
care of mental defectives, ascertainment, the pr
of supervision, institutional care or guardianshi
training and occupation for those not in instit
are involved. Arrangements for care and aft
should also be considered.

While the supervision of mental patients or
or boarded out, and of mental defectives on licen
ultimately the responsibility of the hospital or instit
coöperation between local authorities and regional
may save man-power, scarce in this as in other fie

Effective arrangements will involve consultatio
continued contact between local health autho
the regional hospital boards (who will provide
services of specialists), and hospital management
mittees. So far as local health authorities are conc
in future, responsibility both for the mentally ill an
mental defective will be exercised through the s
tory health committee, advised by the medical office
health. The committee are advised to appoint a me
health subcommittee to draft their proposals and u
take the subsequent detailed administration. A mo
